Guide

SUSE Linux Enterprise Server for SAP Applications 12 SP4
## Contents

**About This Guide** viii

1 **What Is SUSE Linux Enterprise Server for SAP Applications?** 1  
1.1 Software Components 2  
   SUSE Linux Enterprise Server 2  
   High Availability Extension 2  
   Simplified SAP HANA System Replication Setup 3  
   Installation Workflow 5  
   Page-Cache Limit 5  
   Malware Protection with ClamSAP 5  
   SAP HANA Security 6  
   Simplified Operations Management 6  
1.2 Software Repository Setup 8  
1.3 Included Services 11  

2 **Planning the Installation** 13  
2.1 Hardware Requirements 13  
2.2 Downloading the Installation Image 14  
2.3 Installation Methods 14  
2.4 Overview of the Installation Workflow 15  
2.5 Required Data for Installing 16  
2.6 Partitioning 17  
   Partitioning for the Operating System (stage 1) 17  
   Partitioning for the SAP System (stage 2) 17  

3 **Installing the Operating System** 19  
3.1 Using the Installation Workflow 19  
3.2 Using SLES for SAP Media from the Network 27  
3.3 Using an External AutoYaST Profile 28
7.4 **Tuning Kernel Parameters Manually Using `sysctl`** 71

8 **Firewalling** 72
8.1 Configuring SuSEFirewall2 72
8.2 Configuring HANA-Firewall 72
8.3 SAProuter Integration 75

9 **Encrypting Directories Using `cryptctl`** 76
9.1 Setting Up a `cryptctl` Server 77
9.2 Setting Up a `cryptctl` Client 79
9.3 Checking Partition Unlock Status Using Server-side Commands 82
9.4 Unlocking Encrypted Partitions Manually 82
9.5 Maintenance Downtime Procedure 83
9.6 For More Information 83

10 **Protecting Against Malware With ClamSAP** 84
10.1 Installing ClamSAP 84
10.2 Creating a Virus Scanner Group in SAP NetWeaver 84
10.3 Setting Up the ClamSAP Library in SAP NetWeaver 85
10.4 Engaging ClamSAP 86
10.5 For More Information 88

11 **Connecting via RDP** 89

12 **Creating Operating System Images** 91
12.1 Creating Images with KIWI 91
12.2 Cleaning Up an Instance Before Using It as a Master Image 92
Configuring clone-master-clean-up 93 • Using clone-master-clean-up 93 • For More Information 93

About This Guide

SUSE® Linux Enterprise Server for SAP Applications is the reference platform for the software development of SAP. It is optimized for SAP applications. This guide provides detailed information about installing and customizing SUSE Linux Enterprise Server for SAP Applications. SUSE Linux Enterprise High Availability Extension is also part of SUSE Linux Enterprise Server for SAP Applications.

1 Overview

The SUSE Linux Enterprise Server for SAP Applications Guide is divided into the following chapters:

- What Is SUSE Linux Enterprise Server for SAP Applications?
  An overview of SUSE Linux Enterprise Server for SAP Applications.

- Planning the Installation
  Information on hardware requirements, the installation workflow, partitioning, and other installation planning aspects.

- Installing the Operating System
  Installing the SUSE Linux Enterprise Server operating system that forms the basis of SUSE Linux Enterprise Server for SAP Applications.

- Installing SAP Applications
  Installing SAP applications on SUSE Linux Enterprise Server for SAP Applications, either directly after the installation of the operating system or in a running system.

- Setting Up an Installation Server for SAP Media Sets
  Setting up a server for all Installation Media used within your organization.

- Setting Up an SAP HANA Cluster
  Setting up an SAP HANA cluster with system replication using the YaST wizard.

- Tuning
  Tuning the system to enable the best performance for SAP applications.

- Firewalling
  Keeping the system and applications safe using firewalls.
Encrypting Directories Using cryptctl
Keeping server data encrypted at rest.

Protecting Against Malware With ClamSAP
Keeping your users safe from malware.

Connecting via RDP
Using remote access to administrate machines.

Creating Operating System Images
Creating KIWI images and scrubbing private data off fully configured images.

Important Log Files
Gives a short overview of important log files.

2 Additional Documentation and Resources

Chapters in this manual contain links to additional documentation resources that are either available on the system or on the Internet.

- For the latest updates to this guide, see https://www.suse.com/documentation/sles_for_s-ap/.

- You can find numerous whitepapers, a best-practices guide, and other resources at the SUSE Linux Enterprise Server for SAP Applications resource library: https://www.suse.com/products/sles-for-sap/resource-library/.

- For documentation on SUSE Linux Enterprise Server, see https://www.suse.com/documentation/sles-12/.

- For documentation on SUSE Linux Enterprise High Availability Extension, see https://www.suse.com/documentation/sle-ha-12/.

3 Feedback

Several feedback channels are available:

Bugs and Enhancement Requests
For services and support options available for your product, refer to http://www.suse.com/support/.
To report bugs for a product component, go to https://scc.suse.com/support/requests, log in, and select Submit New SR.

User Comments

We want to hear your comments about and suggestions for this manual and the other documentation included with this product. Use the User Comments feature at the bottom of each page in the online documentation or go to http://www.suse.com/doc/feedback.html and enter your comments there.

Mail

For feedback on the documentation of this product, you can also send a mail to doc-team@suse.de. Make sure to include the document title, the product version and the publication date of the documentation. To report errors or suggest enhancements, provide a concise description of the problem and refer to the respective section number and page (or URL).

4 Documentation Conventions

The following typographical conventions are used in this manual:

- `/etc/passwd`: directory names and file names
- `placeholder`: replace `placeholder` with the actual value
- `PATH`: the environment variable PATH
- `ls, --help`: commands, options, and parameters
- `user`: users or groups
- `[Alt], [Alt–F1]`: a key to press or a key combination; keys are shown in uppercase as on a keyboard
- `File, File > Save As`: menu items, buttons

- `amd64, em64t, ipf` This paragraph is only relevant for the architectures `amd64`, `em64t`, and `ipf`. The arrows mark the beginning and the end of the text block.
- `System z, ipseries` This paragraph is only relevant for the architectures `z Systems` and `ipseries`. The arrows mark the beginning and the end of the text block.

- `Dancing Penguins` (Chapter Penguins, †Another Manual): This is a reference to a chapter in another manual.
1 What Is SUSE Linux Enterprise Server for SAP Applications?

SUSE® Linux Enterprise Server for SAP Applications is a bundle of software and services that addresses the specific needs of SAP users. It is the only operating system that is optimized for all SAP software solutions.

Target use cases include:

- Unix to Linux migrations and replatforming
- SAP appliances
- SAP cloud deployments

SUSE Linux Enterprise Server for SAP Applications consists of software components and service offerings which are described in the following sections. The figure Offerings of SUSE Linux Enterprise Server for SAP Applications shows an overview of which software components and services are also available with other products from SUSE (green) and which are exclusively available with SUSE Linux Enterprise Server for SAP Applications (blue).
1.1 Software Components

As depicted in Figure 1.1, “Offerings of SUSE Linux Enterprise Server for SAP Applications”, SUSE Linux Enterprise Server for SAP Applications is based on SUSE Linux Enterprise Server but contains several additional software components such as SUSE Linux Enterprise High Availability Extension, the kernel page-cache limit feature, and the installation workflow. These software components are briefly explained in the following sections.

1.1.1 SUSE Linux Enterprise Server

The current release is based on SUSE Linux Enterprise Server 12 SP4. SUSE Linux Enterprise Server is the most interoperable platform for mission-critical computing, both physical and virtual.

1.1.2 SUSE Linux Enterprise High Availability Extension

This component consists of:

- Flexible, policy-driven clustering
- Cluster-aware file system and volume management
- Continuous data replication
- Setup and installation
- Management and administration tools
- Resource agents, also for SAP
- Virtualization-aware

SUSE Linux Enterprise High Availability Extension provides two resource agents specifically for working with SAP applications:

- **SAPInstance** which allows starting and stopping instances of SAP products.
- **SAPDatabase** which allows starting and stopping all databases supported by SAP applications (SAP HANA, SAP MaxDB, SAP ASE, Oracle, Sybase, IBM DB2).

1.1.3 Simplified SAP HANA System Replication Setup

SUSE Linux Enterprise Server for SAP Applications supports SAP HANA System Replication using components of SUSE Linux Enterprise High Availability Extension and two additional resource agents (RA). Additionally, SUSE Linux Enterprise Server for SAP Applications ships with a YaST wizard that simplifies the cluster setup.

1.1.3.1 SAPHana Resource Agent

This resource agent from SUSE supports scale-up scenarios by checking the SAP HANA database instances for whether a takeover needs to happen. Unlike with the pure SAP solution, takeovers can be automated.

It is configured as a master/slave resource: The master assumes responsibility for the SAP HANA databases running in primary mode, whereas the slave is responsible for instances that are operated in synchronous (secondary) status. In case of a takeover, the secondary (slave resource instance) can automatically be promoted to become the new primary (master resource instance). This resource agent supports system replication for the following in scale-up scenarios:

- **Performance-Optimized Scenario.** Two servers (A and B) in the same SUSE Linux Enterprise High Availability Extension cluster, one primary (A) and one secondary (B). The SAP HANA instance from the primary server (A) is replicated synchronously to the secondary server (B).

- **Cost-Optimized Scenario.** The basic setup of A and B is the same as in the *Performance-Optimized Scenario*. However, the secondary server (B) is also used for non-productive purposes, such as for an additional SAP HANA database for development or QA. The production database is only kept on permanent memory, such as a hard disk. If a takeover needs
to occur, the non-productive server will be stopped before the takeover is processed. The system resources for the productive database are then increased as quickly as possible via an SAP hook call-out script.

- **Chain/Multi-Tier Scenario.** Three servers (A, B, and C), of which two are located in the same SUSE Linux Enterprise High Availability Extension cluster (A and B). The third server (C) is located externally. The SAP HANA system on the primary server (A) is replicated synchronously to the secondary server (B). The secondary server (B) is replicated asynchronously to the external server (C).

  If a takeover from A to B occurs, the connection between B and C remains untouched. However, B is not allowed to be the source for two servers (A and C), as this would be a “star” topology which is not supported with current SAP HANA versions (such as SPS11). Using SAP HANA commands, you can then manually decide what to do:

  - The connection between B and C can be broken, so that B can connect to A.
  - If replication to the external site (C) is more important than local system replication, the connection between B and C can be kept.

For all of the scenarios, SUSE Linux Enterprise Server for SAP Applications supports both single-tenant and multi-tenant (MDC) SAP HANA databases. That is, you can use SAP HANA databases that serve multiple SAP applications.

For more information, also see the project home page [https://github.com/fmhuschel/SAPHanaSR/](https://github.com/fmhuschel/SAPHanaSR/).

### 1.1.3.2 **SAPHanaTopology Resource Agent**

To make configuring the cluster as simple as possible, SUSE has developed the `SAPHanaTopology` resource agent. This agent runs on all nodes of a SUSE Linux Enterprise High Availability Extension cluster and gathers information about the status and configurations of SAP HANA system replications. It is designed as a normal (stateless) clone.

### 1.1.3.3 **YaST Wizard to Set Up SAP HANA Clusters**

SUSE Linux Enterprise Server for SAP Applications now additionally ships a YaST wizard that manages the initial setup of such clusters according to best practices. The wizard is part of the package `yast2-sap-ha` and can be started using YaST, via *HA Setup for SAP Products*. 

---

**Simplified SAP HANA System Replication Setup SLES for SAP 12 SP4**
For more information, see Chapter 6, Setting Up an SAP HANA Cluster.

1.1.3.4 For More Information

For more information, see:

1.1.4 Installation Workflow

The installation workflow offers a guided installation path for both the SUSE Linux Enterprise Server operating system and the SAP application. For more information, see Section 2.4, “Overview of the Installation Workflow”.

Additionally, the installation workflow can be extended by third-party vendors or customers using Supplementary Media. For more information about creating Supplementary Media, see Appendix C, Supplementary Media.

1.1.5 Page-Cache Limit

You can limit the kernel file system cache size to influence swapping behavior. With this feature, you can often gain better performance by allocating memory to an application.

For more information, see Section 7.1, “Kernel: Page-Cache Limit”.

1.1.6 Malware Protection with ClamSAP

ClamSAP integrates the ClamAV anti-malware toolkit into SAP NetWeaver and SAP Mobile Platform applications to enable cross-platform threat detection. For example, you can use ClamSAP to allow an SAP application to scan for malicious uploads in HTTP uploads.

For more information, see Chapter 10, Protecting Against Malware With ClamSAP.
1.1.7 SAP HANA Security

SUSE Linux Enterprise Server for SAP Applications contains additional features to help set up well-secured SAP HANA installations.

1.1.7.1 Firewall for SAP HANA

Securing SAP HANA can require many additional firewall rules. To simplify firewall setups for SAP HANA, SUSE Linux Enterprise Server for SAP Applications contains the package `HANA-Firewall` which provides preconfigured rules and integrates with SuSEFirewall2.

For more information, see Section 8.2, “Configuring HANA-Firewall”.

1.1.7.2 Hardening Guide for SAP HANA

For information on hardening the underlying operating system, see the SUSE Linux Enterprise Server for SAP Applications resource library: https://www.suse.com/products/sles-for-sap/resource-library/. There, find the document OS Security Hardening for SAP HANA.

1.1.8 Simplified Operations Management

SUSE Linux Enterprise Server for SAP Applications combines several features that enable simplified operations management.

1.1.8.1 System Tuning with sapconf

The system tuning application `sapconf` allows you to automatically and comprehensively tune your system as recommended by SAP for use with SAP S/4HANA, SAP NetWeaver, or SAP HANA/SAP BusinessOne. To do this, `sapconf` activates tuned profiles. These allow tuning several kernel parameters, depending on the hardware components you are using, such as the amount of available RAM.

For more information, see Section 7.2, “Tuning Systems with sapconf”.
1.1.8.2 Storage Encryption for Hosted Applications with cryptctl

Today, databases and similar applications are often hosted on external servers that are serviced by third-party staff. Certain data center maintenance tasks require third-party staff to directly access affected systems. In such cases, privacy requirements necessitate disk encryption.

cryptctl allows encrypting sensitive directories using LUKS and offers the following additional features:

- Encryption keys are located on a central server which can be located on customer premises.
- Encrypted partitions are automatically remounted after an unplanned reboot.

For more information, see Chapter 9, Encrypting Directories Using cryptctl.

1.1.8.3 Patterns Providing Dependencies of SAP Applications

To simplify working with software dependencies of SAP applications, SUSE has created patterns that combine relevant dependency RPM packages for specific applications:

- SAP BusinessOne Server Base
- SAP HANA Server Base
- SAP NetWeaver Server Base

⚠️ Important: Packages May Be Missing from Patterns

The selection of packages of the software patterns are defined while a specific release (Service Pack or major version) of SUSE Linux Enterprise Server for SAP Applications is developed. This package selection is stable over the lifetime of this particular release. When working with SAP applications that have been released more recently than your SUSE Linux Enterprise Server for SAP Applications version, dependencies can be missing from the patterns.

For definitive information about the dependencies of your SAP application, see the documentation provided to you by SAP.
1.1.8.4 ClusterTools2

ClusterTools2 provides tools that help set up and manage a Corosync/pacemaker cluster. Among them are wow which helps create highly available system resources, and ClusterService which allows managing a cluster.

Additionally, ClusterTools2 provides scripts that automate common cluster tasks:

- Scripts that perform checks. For example, to find out whether a system is set up correctly for creating a pacemaker cluster.
- Scripts that simplify configuration. For example, to create a Corosync configuration.
- Scripts that monitor the system and scripts that show or collect system information. For example, to find known error patterns in log files.

For more information, see the man page of the respective tool, included with the package ClusterTools2. Also see the project home page at https://github.com/fmherschel/ClusterTools2.

1.2 Software Repository Setup

Software included with operating systems based on SUSE Linux Enterprise is delivered as RPM packages, a form of installation package that can have dependencies on other packages. On a server or an installation medium, these packages are stored in software repositories (sometimes also called “channels”).

By default, computers running SUSE Linux Enterprise Server for SAP Applications are set up to receive packages from multiple repositories. Of each of the standard repositories, there is a “Pool” variant that represents the state of the software when it was first shipped. There is also an “Update” variant that includes the newest maintenance updates for the software in the “Pool” variant.

If you registered your system during installation, your repository setup should include the following:

TABLE 1.1: STANDARD REPOSITORIES

<table>
<thead>
<tr>
<th>Content</th>
<th>Base repository (“Pool”)</th>
<th>Update repository</th>
</tr>
</thead>
<tbody>
<tr>
<td>Base packages of SUSE Linux Enterprise Server</td>
<td>SLES12-SP4-Pool</td>
<td>SLES12-SP4-Updates</td>
</tr>
<tr>
<td>Content</td>
<td>Base repository (&quot;Pool&quot;)</td>
<td>Update repository</td>
</tr>
<tr>
<td>---------</td>
<td>--------------------------</td>
<td>-------------------</td>
</tr>
<tr>
<td>Packages specific to SUSE Linux Enterprise Server for SAP Applications</td>
<td>SLE12-SP4-SAP-Pool</td>
<td>SLE-12-SP4-SAP-Updates</td>
</tr>
<tr>
<td>Packages specific to SUSE Linux Enterprise High Availability Extension</td>
<td>SLE-HA12-SP4-Pool</td>
<td>SLE-HA12-SP4-Updates</td>
</tr>
</tbody>
</table>

The tables in this section do not show *Debuginfo* and *Source* repositories which are also set up but disabled by default. The *Debuginfo* repositories contain packages that can be used for debugging regular packages. The *Source* repositories contain source code for packages.

Depending on your installation method, you may also see SLE-12-SP4-SAP-12.4-0 which is the installation medium. It contains packages from all of the base software repositories listed above.

Because there are own repositories for SUSE Linux Enterprise Server for SAP Applications, SUSE can ship packages and patches that are specific to SUSE Linux Enterprise Server for SAP Applications.

**Note: ESPOS Updates Shipped Directly in Update Repositories**

Unlike in SUSE Linux Enterprise Server for SAP Applications 11, updates related to Extended Service Pack Overlay Support (ESPOS) are shipped directly from the Update repositories. This means there is no separate ESPOS repository to set up.

In addition to the standard repositories, you can enable the following SLE Modules and SLE Extensions either during the installation or from the running system using YaST or the command **SUSEConnect**.
### TABLE 1.2: MODULE REPOSITORIES

<table>
<thead>
<tr>
<th>Content</th>
<th>Base repository (“Pool”)</th>
<th>Update repository</th>
</tr>
</thead>
<tbody>
<tr>
<td>Containers Module: Docker, tools, prepackaged images</td>
<td>SLE-Module-Containers12-Pool</td>
<td>SLE-Module-Containers12-Updates</td>
</tr>
<tr>
<td>HPC Module: tools and libraries related to High Performance Computing</td>
<td>SLE-Module-HPC12-Pool</td>
<td>SLE-Module-HPC12-Updates</td>
</tr>
<tr>
<td>Legacy Module: Sendmail, old IMAP stack, old Java, ...</td>
<td>SLE-Module-Legacy12-Pool</td>
<td>SLE-Module-Legacy12-Updates</td>
</tr>
<tr>
<td>Public Cloud Module: public cloud initialization code and tools</td>
<td>SLE-Module-Public-Cloud12-Pool</td>
<td>SLE-Module-Public-Cloud12-Updates</td>
</tr>
<tr>
<td>Toolchain Module: GNU Compiler Collection (GCC)</td>
<td>SLE-Module-Toolchain12-Pool</td>
<td>SLE-Module-Toolchain12-Updates</td>
</tr>
<tr>
<td>Web and Scripting Module: PHP, Python, Ruby on Rails</td>
<td>SLE-Module-Web-Scripting12-Pool</td>
<td>SLE-Module-Web-Scripting12-Updates</td>
</tr>
</tbody>
</table>

### TABLE 1.3: EXTENSION REPOSITORIES

<table>
<thead>
<tr>
<th>Content</th>
<th>Base repository (“Pool”)</th>
<th>Update repository</th>
</tr>
</thead>
<tbody>
<tr>
<td>SLE SDK</td>
<td>SLE-SDK12-SP4-Pool</td>
<td>SLE-SDK12-SP4-Updates</td>
</tr>
<tr>
<td>SUSE Package Hub</td>
<td>SUSE-PackageHub-12-SP4-Pool</td>
<td>SUSE-PackageHub-12-SP4-Updates</td>
</tr>
</tbody>
</table>

For more information about SUSE Package Hub, see Section A.2, “SUSE Package Hub”. For information about life cycle and support of modules and extensions, see Section 1.3, “Included Services”.

Software Repository Setup  
SLES for SAP 12 SP4
1.3 Included Services

*Extended Service Pack Overlap Support (ESPOS)*

Subscriptions for SUSE Linux Enterprise Server for SAP Applications include Extended Service Pack Overlap Support, which extends the overlap between the support periods of two consecutive service packs by three years. During this period, you receive support and all relevant maintenance updates under the terms of Long Term Service Pack Support (LTSS). This feature is only available with SUSE Linux Enterprise Server for SAP Applications. Extended Service Pack Overlap Support allows you to perform service pack migrations within three and a half (3½) years instead of only six months. This enables you to schedule migrations more easily and perform testing before a migration under less restrictive time constraints.

At an additional cost, SUSE also offers Long Term Service Pack Support (LTSS). With LTSS, you receive support for a particular service pack after the ESPOS period ends. Since SUSE Linux Enterprise Server for SAP Applications includes one and a half (1½) years of general support and three years of ESPOS for each service pack, LTSS may only be offered for the last service pack. For more information about the life cycle of SUSE products, see:

- Exact dates: [https://www.suse.com/lifecycle/](https://www.suse.com/lifecycle/)

*SUSE Linux Enterprise Server Priority Support for SAP Applications*

Subscriptions for SUSE Linux Enterprise Server for SAP Applications include SUSE Linux Enterprise Server Priority Support for SAP Applications, which offers technical support for SUSE Linux Enterprise Server for SAP Applications directly from SAP. The joint support infrastructure, provided by support engineers from SUSE Technical Support and SAP, is based upon SAP Resolve and offers seamless communication with both SAP and SUSE. This “One Face to the Customer” support model reduces complexity and lowers the total cost of ownership.

For more information, see *SAP Note 1056161: SUSE Priority Support for SAP Applications* ([https://launchpad.support.sap.com/#/notes/1056161](https://launchpad.support.sap.com/#/notes/1056161)).
Important: Life Cycle and Support for Modules and Extensions

Modules and extensions have a different life cycle than SLES for SAP and SUSE provides different support offerings for them:

- **Modules**
  - **Life Cycle.** Varies depending on the module.
  - **Support.** Only up-to-date packages are supported. Support is included with your subscription for SUSE Linux Enterprise Server for SAP Applications. You do not need an additional registration key.

- **Extensions**
  - **Life Cycle.** Releases are usually coordinated with SUSE Linux Enterprise Server for SAP Applications.
  - **Support.** Support is available but not included with your subscription for SUSE Linux Enterprise Server for SAP Applications. You need an additional registration key.

- ** Unsupported Extensions (SUSE Package Hub and SUSE Software Development Kit)**
  - **Life Cycle.** Releases are usually coordinated with SUSE Linux Enterprise Server for SAP Applications.
  - **Support.** There is no support beyond fixes for security and packaging issues. You do not need an additional registration key.
2 Planning the Installation

Read this chapter carefully, as it helps you plan the installation: It lists requirements and helps you collect data about your system.

2.1 Hardware Requirements

This section lists minimum hardware requirements for the installation of SUSE Linux Enterprise Server for SAP Applications and gives basic guidance on the expected hardware requirements of certain SAP software. For the most up-to-date information about the hardware requirements of SAP software, see the official sizing guidelines at https://service.sap.com/sizing.

CPU

Intel 64/AMD64
IBM POWER servers with PowerKVM compatibility

Hard Disk

SUSE Linux Enterprise Server for SAP Applications requires at least 45 GB of hard disk space for the system volume. In addition to that, reserve an appropriate amount of hard disk space for the swap partition.

To install an SAP application such as SAP NetWeaver, you need at least 200 GB of free disk space in addition to the required space for the operating system for the application's /data partition.

To install SAP HANA, you need either:

- An SAP BusinessOne-certified machine
- A compatible machine that meets the requirements for SAP HANA TDI (Tailored Datacenter Integration). That is, you need the following amounts of free disk space in addition to the required space for the operating system:
  - 52 GB of free disk space for the partition /usr/sap
  - Space for three partitions for SAP HANA data: /hana/data (same size as RAM), /hana/log (same size as RAM up to a maximum of 512 GB), and /hana/shared (same size as RAM up to a maximum of 1 TB).
RAM
The SUSE Linux Enterprise Server operating system itself requires a minimum of 1024 MB of total RAM or a minimum of 512 MB of RAM per CPU core (choose whichever is higher). Any SAP software you install will require additional RAM. To install SAP HANA, your machine needs a minimum of 24 GB of RAM.

For more information about partitioning, see Section 2.6, “Partitioning”.

2.2 Downloading the Installation Image

2. Burn the image onto a physical DVD and ensure that it is bootable. Alternatively, use a virtual DVD-ROM device for installation in a virtual machine.

2.3 Installation Methods

There are multiple ways of installing SUSE Linux Enterprise Server for SAP Applications:

- **Using the Installation Workflow** (standard way of installation)
- **Using an External AutoYaST Profile**
2.4 Overview of the Installation Workflow

The installation workflow of SUSE Linux Enterprise Server for SAP Applications consists of the following steps:

1. Installation of the operating system (SUSE Linux Enterprise Server). See Section 3.1, “Using the Installation Workflow”.

2. SAP Installation Wizard, part 1: Copying all required SAP media to the local disk or selecting a shared storage medium to use. See Section 4.3, “Using the SAP Installation Wizard”, in particular Step 1.

3. SAP Installation Wizard, part 2: Collecting all parameters for the actual installation by querying the user interactively. See Section 4.3, “Using the SAP Installation Wizard”, in particular Step 10.

⚠️ Important: Installation of Only SUSE Linux Enterprise Server

You can choose to only install a base SUSE Linux Enterprise Server system. In that case, only the first step of the installation workflow is executed.

This can be necessary when you want to install an Oracle database on a SUSE Linux Enterprise Server for SAP Applications machine. To do so, install the base product SUSE Linux Enterprise Server first, then install the Oracle database and later convert your installation to SLES for SAP. This is necessary because the installer of Oracle databases queries for the existence of certain files, not all of which are included in a SLES for SAP installation.

For more information about converting, see Section 3.4, “Converting a SLES Installation to a SLES for SAP Installation”.

Most of these steps do not need to be run immediately after each other, which allows for flexibility in how you install systems. This means that you can prepare a single installation as a first step and then continue from there. For example:

- Install the operating system (SUSE Linux Enterprise Server) only.
or

- Install the operating system (SUSE Linux Enterprise Server), copy SAP media, and collect SAP installation parameters.

Then, create disk images, copy them to other systems, and adjust SAP installation parameters. Finally, finish the installation on each machine individually.

2.5 Required Data for Installing

Operating System
The SUSE Linux Enterprise Server installation requires the following data for every physical server:

- Network configuration parameters, such as host name, domain, IP address, subnet mask, domain searchlist (DNS), IP for name server, IP for gateway
- Administrator (root) password for the SUSE Linux Enterprise Server installation

SAP Application
The installation of an SAP application generally requires specifying:

- SAP SID
- SAP Instance Number
- A password for the SAP application

Depending on the SAP application you are installing, more parameters may be necessary, such as T-Shirt Sizing or parameters for virtual networking.

SAP HANA Database
The installation of SAP HANA requires specifying:

- SAP SID
- SAP Instance Number
- Whether to enable Multitenant Database Containers (MDC). The multi-tenant support of SAP HANA allows having multiple databases that run as one SAP HANA installation. (To use SAP HANA MDC, you need SAP HANA Life Cycle Manager.) For a single-tenant installation, choose No.
For a multi-tenant instance administrated by one \textit{SIDadm} user, choose \textit{Yes with low isolation}.

For a multi-tenant instance administrated in which each database has its own \textit{SIDadm} user, choose \textit{Yes with high isolation}.

- A password for the SAP HANA database

For more information about installing SAP software, see the SAP documentation at https://help.sap.com\textsuperscript{r} and https://support.sap.com\textsuperscript{r}.

### 2.6 Partitioning

SUSE Linux Enterprise Server for SAP Applications creates the partitioning table in two stages:

1. \textit{Partitioning for the Operating System (stage 1)} (during the installation of the operating system)
2. \textit{Partitioning for the SAP System (stage 2)} (during the installation of the SAP product)

#### 2.6.1 Partitioning for the Operating System (stage 1)

During the installation of the operating system, partitions for the operating system are created. A logical volume group (LVG) named /\texttt{dev/system} will be created. This LVG contains two logical volumes (LVs):

- /\texttt{dev/system/root}: by default 60 GB to account for the operating system and SAP media
- /\texttt{dev/system/swap}: by default 2 GB, avoid setting a smaller size. See also \textit{SAP Note 1984787: SUSE Linux Enterprise Server 12: Installation notes} (https://launchpad.support.sap.com/#/notes/1984787\textsuperscript{r}).

Additionally, a \texttt{boot} or UEFI partition will be created as necessary.

#### 2.6.2 Partitioning for the SAP System (stage 2)

The partitioning for the SAP system can be created by:

- The SAP Installation Wizard (see \textit{Section 4.3, “Using the SAP Installation Wizard”}.
- Using YaST on the command line (see \textit{Section 4.5, “Partitioning for an SAP Application Without the SAP Installation Wizard”}).
This part of the partitioning can only be created after the operating system has been installed. That means the partitions are created either in the installation workflow after the reboot or in the running system.

Depending on the product you are installing and your particular use case, the amount of hard disk space necessary can vary.

For information on partitioning for the SAP system using AutoYaST, see Appendix B, Partitioning for the SAP System Using AutoYaST.
3 Installing the Operating System

The following section provides instructions for installing the base operating system. Using the installation workflow, you can install either using a local installation medium or over the network. Alternatively, you can install using AutoYaST.

3.1 Using the Installation Workflow

The installation workflow is a guided installation of the operating system with optimized settings for SAP applications. During the installation workflow, you can choose whether you want to install an SAP application. If so, you will be asked to provide SAP installation media when the SUSE Linux Enterprise Server installation is finished. You can also choose whether to install third-party extensions.

This section assumes that you are starting the installation from a local medium. To learn how to start the installation from a remote medium, see Section 3.2, “Using SLES for SAP Media from the Network”.

For more information, see Section 2.4, “Overview of the Installation Workflow”.

This section guides you through the installation of the SUSE Linux Enterprise Server for SAP Applications operating system.

PROCEDURE 3.1: STARTING THE OS INSTALLATION

1. On Intel 64/AMD64, boot from the DVD. From the DVD boot menu, select Installation.

While the initial operating system is starting, you can view boot messages by pressing \[Esc\]. When this process has completed, the graphical installation workflow will start.

2. Select the default system language under *Language*. 

---

**FIGURE 3.2: LANGUAGE, KEYBOARD AND LICENSE AGREEMENT**
3. Select the appropriate keyboard layout under *Keyboard Layout*. To test whether the selected layout matches your physical keyboard, use the text box *Keyboard Test*.

4. Read the license agreement. If you agree, select *I Agree to the License Terms*. Proceed with *Next*. Otherwise, cancel the installation with *Abort* → *Abort Installation*.

5. *(Optional)* If automatic network configuration via DHCP fails, the screen *Network Settings* will open. If instead the screen *Registration* appears, your network connection works. To change network settings anyway, click *Network Configuration*. When you are finished configuring networking, proceed with *Next*.

⚠️ **Important: Configure Networking as Recommended by SAP**

Make sure to configure the network connection as recommended in the documentation provided to you by SAP.

For information about configuring networking, see *Administration Guide, Chapter “Basic Networking”, Section “Configuring a Network Connection with YaST”* ([https://www.suse.com/documentation/sles-12/](https://www.suse.com/documentation/sles-12/)).

6. On the screen *Registration*, enter your *E-mail Address* and *Registration Code*. Successful registration is a prerequisite for receiving product updates and the entitlement to technical support. Proceed with *Next*.

⚠️ **Important: Register at This Step**

Make sure to register your system at this step in the installation. Otherwise, you will not receive package updates immediately.
7. When asked whether to enable update repositories, choose Yes.

8. After the system is successfully registered, YaST lists additional software that is available for SUSE Linux Enterprise Server for SAP Applications from the SUSE Customer Center. The list contains modules, which are free, and extensions, which require a registration key that is liable for costs. To enable a module or an extension, activate its entry. Proceed with Next.

9. The following screen allows you to choose the Product Installation Mode. You can now choose between:

   - A SUSE Linux Enterprise Server Installation. To install a SLES system without SAP-specific customization, choose *Proceed with standard SLES installation*. For details, see *Installation Quick Start, Section “Installing SUSE Linux Enterprise Server”* ([https://www.suse.com/documentation/sles-12/](https://www.suse.com/documentation/sles-12/)).

⚠️ Important: Installing Oracle Databases
To be able to install an Oracle database later, choose *Proceed with standard SLES installation* and later convert your installation to SLES for SAP.
This is necessary because the installer for Oracle databases queries for the existence of certain files, not all of which are included in a SLES for SAP installation.

For more information about converting, see Section 3.4, “Converting a SLES Installation to a SLES for SAP Installation”.

- **A SUSE Linux Enterprise Server for SAP Applications Installation.** To install a SLES system with SAP-specific customization, choose *Proceed with standard SLES for SAP Applications installation*.

  - To install an SAP Application together with the system, activate *Launch the SAP Installation Wizard right after the operating system is installed*.

  - To enable RDP access (Remote Desktop Protocol) to this machine, activate *Enable RDP service and open port in firewall*.

For more information about connecting via RDP, see *Chapter 11, Connecting via RDP*.

Proceed with *Next*.
PROCEDURE 3.2: FINISHING THE OS INSTALLATION

1. You can now choose whether to install an *Add On Product*. Proceed with *Next*.

2. Review the proposed partition setup for the volumes `/dev/system/root` and `/dev/system/swap`. The volume `/dev/system/data` will be created later, as described in *Section 2.6, “Partitioning”*. Suitable values are preselected. However, if necessary, change the partition layout. You have the following options:

   * **Edit Proposal Settings**
     - Allows you to change the options for the proposed settings, but not the suggested partition layout itself.

   * **Create Partition Setup**
     - Select a disk to which to apply the proposal.

   * **Expert Partitioner**

       For partitioning advice specific to SUSE Linux Enterprise Server for SAP Applications, see *Section 2.6, “Partitioning”*.

To accept the proposed setup without changes, proceed with *Next*. 

Note: Release Notes

From this point on, the Release Notes can be viewed from any screen during the installation process by selecting Release Notes.

3. Select the clock and time zone to use on your system. To manually adjust the time or to configure an NTP server for time synchronization, choose Other Settings. For detailed information, see Deployment Guide, Chapter “Installation with YaST”, Section “Clock and Time Zone” (https://www.suse.com/documentation/sles-12/).

Proceed with Next.

4. Type a password for the system administrator account (called root) and repeat the password under Confirm Password. You can use the text box Test Keyboard Layout to make sure that all special characters appear correctly.

For more information, see Deployment Guide, Chapter “Installation with YaST”, Section “Password for the System Administrator root” (https://www.suse.com/documentation/sles-12/).

Proceed with Next.
Important: Do Not Forget the root Password

The user root has the permission to carry out all administrative tasks. Without this password, you cannot log in to the system as root. The password entered here cannot be retrieved later.

5. On the screen Installation Settings, you can review and, if necessary, change several proposed installation settings. Each setting is shown alongside its current configuration. To change parts of the configuration, click the appropriate headline or other underlined items.

Important: Firewall Configuration

The software firewall of SLES for SAP is enabled by default. However, often, the ports your SAP product requires to be open are not opened automatically. This means that there may be network issues until you open the required ports manually. For details, see Section 8.1, “Configuring SuSEFirewall2”.

6. When you are satisfied with the system configuration, click Install. Depending on your software selection, you may need to agree to further license agreements before you are asked to confirm that you want to start the installation process.
Warning: Deletion of Data

The installation process fully or partially overwrites existing data on the disk.

In the installation confirmation box, click Install.
When the installation of the operating system is finished, the system will reboot automatically:

- If you chose to only prepare the system for installation, the system will boot to a desktop login screen.
- If you chose to install an SAP application immediately after the operating system, the installation will continue after the reboot.
In this case, continue with Chapter 4, Installing SAP Applications.

3.2 Using SLES for SAP Media from the Network

This section provides a short description of how to install from an installation medium served over the network. This allows, for example, using a regular SLES medium to install SLES for SAP.

1. Copy the content of the SUSE Linux Enterprise Server for SAP Applications DVD to a Web server (for example, example.com), to the directory /srv/www/htdocs/sap_repo.

2. Boot from a SUSE DVD.

3. Select one of the boot menu options using the keys ↓/↑. Then add to the command line. To do so, specify the parameters listed below:
   - To allow network usage, add ifcfg=*=dhcp (though this should be the default).
   - Add the parameter install=SERVER/DIRECTORY.

4. Follow the instructions in Section 3.1, “Using the Installation Workflow”.

For more information, see Deployment Guide, Chapter “Remote Installation” (https://www.suse.com/documentation/sles-12/).

To avoid having to use a DVD to initialize the system, you can boot over the network via PXE. For details, see AutoYaST Guide, Chapter “Booting via PXE over the Network” (https://www.suse.com/documentation/sles-12/).
3.3 Using an External AutoYaST Profile

For more information about installing with AutoYaST, see:

For more information about partitioning for SAP applications with AutoYaST, see *Section 2.6, “Partitioning”.*

3.4 Converting a SLES Installation to a SLES for SAP Installation

To convert an installation of SUSE Linux Enterprise Server 12 SP4 or JeOS 12 SP4 to an installation of SLES for SAP, use the script *Migrate_SLES_to_SLES-for-SAP.sh.* The script will register the system correctly and subscribe it to the appropriate repositories.

Make sure that you have an e-mail address for registration and a registration code for SLES for SAP.

1. Install the package *migrate-sles-to-sles4sap.*
2. Execute the following command:
   ```
   root # Migrate_SLES_to_SLES-for-SAP-12.sh
   ```
3. When asked to confirm to continue the migration, press *Y*, then *Enter*.
4. When asked, type the e-mail address to use for registration, then press *Enter*.
5. When asked, type the registration key, then press *Enter*.
   Wait until the script is finished. Afterward, you are subscribed to the SUSE Linux Enterprise Server for SAP Applications software repositories and the package *SLES-release* is removed in favor of *SLES_SAP-release.*
Important: Script Does Not Install Default SLES for SAP Packages

The script does not install all packages that are included with a default SLES for SAP installation. However, you can install these yourself manually. To install the default package selection, use:

```
root # zypper in patterns-sles-sap_server
```
4 Installing SAP Applications

This section guides you through the installation of SAP media sets you received from SAP.

- If you are installing an SAP application within the installation workflow, continue with Section 4.2, “First Steps”.
- If you are installing an SAP application within an installed system, continue with Section 4.3, “Using the SAP Installation Wizard”.

4.1 Products That Can Be Installed Using SAP Installation Wizard

Using the SAP Installation Wizard, you can install stand-alone SAP HANA database instances. Additionally, the following SAP products (along with a database) can be installed using the SAP Installation Wizard:

- SAP S/4HANA, on-premise edition 1511
- SAP NetWeaver 7.5
- SAP NetWeaver 7.4 Support Release 2
- SAP NetWeaver 7.4 Support Release 1
- SAP NetWeaver 7.4
- SAP Enhancement Package 1 for SAP NetWeaver 7.3
- SAP NetWeaver 7.3
- SAP NetWeaver Composition Environment (CE) 7.2
- SAP EHP1 for SAP NetWeaver Composition Environment (CE) 7.1
- SAP NetWeaver Composition Environment (CE) 7.1
- SAP EHP1 for SAP NetWeaver Mobile/Banking 7.1
- SAP EHP1 SAP NetWeaver Process Integration 7.1
• SAP EHP1 for SAP NetWeaver Adaptive Computing Controller 7.1
• SAP NetWeaver Mobile/Banking 7.1
• SAP NetWeaver Process Integration 7.1
• SAP NetWeaver Adaptive Computing Controller 7.1
• SAP Business Suite powered by SAP HANA
• SAP Business Suite 7i 2016
• SAP Business Suite 7i 2013 Support Release 2
• SAP Business Suite 7i 2013 Support Release 1
• SAP Business Suite 7i 2011 Java
• SAP Business Suite 7i 2010 Java
• SAP Business Suite 7 Support Release 1 Java
• SAP Solution Manager 7.2 Support Release 1
• SAP Solution Manager 7.1 powered by SAP HANA
• SAP NetWeaver AS ABAP 7.4, OEM version 1.0

❗ Important: Installation of Oracle Databases Not Possible

The SAP Installation Wizard does not allow installing products together with Oracle databases. To install an Oracle database, install the base product SUSE Linux Enterprise Server first, then install the Oracle database and later convert your installation to SLES for SAP. This is necessary because the installer of Oracle databases queries for the existence of certain files, not all of which are included in a SLES for SAP installation.

For more information about converting, see Section 3.4, “Converting a SLES Installation to a SLES for SAP Installation”.

4.2 First Steps

These first steps are only relevant during the installation workflow.
1. When the system is booted, it displays the screen Welcome. Proceed with Next.

2. The screen Network Settings will now open. This gives you an opportunity to change the network settings.
   When you are finished configuring networking, proceed with Next.

⚠️ **Important: Configure Networking as Recommended by SAP**

Make sure to configure the network connection according to the documentation of your SAP application.

For information about configuring networking, see *Administration Guide, Chapter “Basic Networking”, Section “Configuring a Network Connection with YaST”* (https://www.suse.com/documentation/sles-12/).

(While the next screen loads, the Welcome screen may appear again for a few seconds.)

3. Choose one of the following options:

- **Create SAP file systems and start SAP product installation**
  Allows installing an SAP application and setting up the system as a server providing SAP installation routines to other systems.
  Continue with Section 4.3, “Using the SAP Installation Wizard”.

- **Only create SAP HANA file systems, do not install SAP products now**
  Create an SAP HANA file system on SAP BusinessOne-certified hardware.

⚠️ **Important: Hardware Requirements**

Make sure your machine fulfills the hardware requirements for SAP HANA detailed in *Section 2.1, “Hardware Requirements”*. Otherwise, this option will not create a new file system and the installation workflow ends at this point.

- **Finish wizard and proceed to OS login**
  Do not install an SAP application and continue to the login screen of SUSE Linux Enterprise Server for SAP Applications.

  Proceed with Next.
4.3 Using the SAP Installation Wizard

Use the SAP Installation Wizard to install an SAP NetWeaver system (including database) or a simple SAP HANA system (single tenant, same password for all initial users, default settings).

To install other SAP applications or to create a more advanced SAP HANA setup, directly use one of the installation methods provided by SAP instead of this wizard.

Tip: Installing an SAP Application in a Fully Installed System

This process is documented as it appears during the installation workflow. However, it also applies to the YaST module *SAP Installation Wizard* which is available in the installed system.

To start the SAP Installer, from the desktop, choose *Applications* > *System* > *YaST*, continue in the YaST control center by choosing *Miscellaneous* > *SAP Installation Wizard*.

Tip: SAP Installation Wizard Configuration

The SAP Installation Wizard configuration is specified and documented in `/etc/sysconfig/sap-installation-wizard`. You can change it according to your needs.

1. In the screen *SAP Installation Wizard*, provide the *Location of the SAP Installation Master* (*Figure 4.1, “Location of SAP Installation Master”*). The location can either be a local, removable, or remote installation source.
Select the appropriate option from the drop-down box. In the text box, specify the path to your source according to the format given in the following table.

**TABLE 4.1: MEDIA SOURCE PATH**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Format of Path</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Local Sources</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>dir://</td>
<td>a local directory</td>
<td>/path/to/dir/</td>
</tr>
<tr>
<td><strong>Removable Sources</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>device://</td>
<td>a locally connected hard disk</td>
<td>devicename/path/to/dir/on/device</td>
</tr>
<tr>
<td>usb://</td>
<td>a USB mass storage device</td>
<td>/path/to/dir/on/USB</td>
</tr>
<tr>
<td>cdrom://</td>
<td>a CD or DVD</td>
<td>//</td>
</tr>
<tr>
<td><strong>Remote Sources</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Format of Path</td>
</tr>
<tr>
<td>---------</td>
<td>-----------------</td>
<td>-----------------------------------------------------</td>
</tr>
<tr>
<td>nfs://</td>
<td>an NFS share</td>
<td>server_name/path/to/dir/on/device</td>
</tr>
<tr>
<td>smb://</td>
<td>an SMB share</td>
<td>[user_name:password@]server_name//path/to/dir/on/server[?workgroup=workgroup_name]</td>
</tr>
</tbody>
</table>

**Tip: Remote Location Specification**

To install from an NFS source, specify the name of the server and the complete path to the media data. For information about setting up a remote installation server, see *Chapter 5, Setting Up an Installation Server for SAP Media Sets*.

If you have installed an SAP application from an installation server before or set up your system to be an installation server, you can also directly choose that server as the provider of the Installation Master. To do so, use the drop-down box below *Choose an installation master*.

2. Under *Advanced Options*, choose from the following options:

- **Collect installation profiles for SAP products but do not execute installation**
  Use this option to set the installation parameters, but not perform the actual installation. With this option, the SAP Installer (SAPinst) will stop without performing the actual SAP product installation. However, the steps that follow fully apply.
  For more information, see *Section 4.4, “Continuing an Installation Using an Installation Profile”*.

- **Serve all installation media (including master) to local network via NFS**
  Set up this system as an installation server for other SUSE Linux Enterprise Server for SAP Applications systems. The media copied to this installation server will be offered through NFS and can be discovered via Service Location Protocol (SLP).
  Proceed with *Next*.
The SAP Installation Wizard will now copy the Installation Master to your local disk. Depending on the type of Installation Master you selected, the installation will continue differently:

- If you are installing an SAP HANA database, skip ahead to Step 8.
- If you are installing an SAP NetWeaver application, continue with the next step.

3. On the screen SAP Installation Wizard, provide the location of additional Installation Media you want to install. This can include an SAP kernel, a database, and database exports.

   **Copy a medium**
   
   Specify a path to additional Installation Media. For more information about specifying the path, see Table 4.1, “Media Source Path”.

   **Skip copying of medium**

   Do not copy additional Installation Media. Choose this option if you do not need additional Installation Media or to install additional Installation Media directly from their source, for example CDs/DVDs or flash disks.

   When choosing this option despite your SAP product requiring additional Installation Media, you will later need to provide the SAP Installer (SAPinst) with the relevant paths.

   Proceed with Next.

   If you chose to copy Installation Media, the SAP Installation Wizard will copy the relevant files to your local hard disk.
4. After copying the Installation Media, you will be asked whether you want to prepare additional Installation Media. To do so, click Yes. Then follow the instructions in Step 3. Otherwise, click No.

5. In the screen What Would You Like to Install, under The SAP product is, choose how you want to install the product:

**SAP Standard System**
- Install an SAP application including its database.

**SAP Standalone Engines**
- Engines that add functionality to a standard product: SAP TREX, SAP Gateway, and Web Dispatcher.

**Distributed System**
- An SAP application that is separated onto multiple servers.

**SAP High-Availability System**
- Installation of SAP NetWeaver in a high-availability setup.

**System Rename**
Allows changing system properties such as the SAP system ID, database ID, instance number or host name. This can be used to install the same product in a very similar configuration on different systems.

FIGURE 4.3: SAP INSTALLATION WIZARD: INSTALLATION TYPE AND DATABASE

6. If you selected SAP Standard System, Distributed System, or SAP High-Availability System, additionally choose a back-end database under The back-end database system is. Proceed with Next.

7. You will now see the screen Choose a Product. The products shown depend on the Media Set and Installation Master you received from SAP. From the list, select the product you want to install. Proceed with Next.
8. You will be asked whether to copy Supplementary Media or Third-Party Media. To do so, click Yes and then follow the instructions in Step 3. Otherwise, click No.

![Figure 4.4: SAP Installation Wizard: Choose a Product](image)

Note: Difference Between Supplementary Media/Third-Party Media and Additional Software Repositories

Both types of delivery mechanisms allow installing software that is neither part of the SUSE Linux Enterprise Server for SAP Applications media nor part of your Media Set from SAP. However, the delivery mechanism is different:

- Supplementary Media/Third-Party Media is installed using an AutoYaST file which allows creating an installation wizard and custom installation scripts.

- Additional software repositories are RPM package repositories that you will remain subscribed to. This means you receive updates for Third-Party Media along with your regular system updates.

For information on creating Supplementary Media, see Appendix C, Supplementary Media.
9. On the screen Additional software repositories for your SAP installation, you can add further software repositories. For example, for add-ons that are packaged as RPM. To do so, click Add new software repositories. For more information about adding repositories, see Deployment Guide, Chapter “Installing and Removing Software”, Section “Adding Software Repositories” (https://www.suse.com/documentation/sles-12/). Proceed with Next.

Note: Location of Copied SAP Media
At this point, all data required for the SAP installation has been copied to /data/SAP_CDs (unless you chose to skip the process of copying). Each Installation Medium is copied to a separate directory. You might find the following directory structure, for example:

```
tux > ls /data/SAP_CDs
742-KERNEL-SAP-Kernel-742
742-UKERNEL-SAP-Unicode-Kernel-742
RDBMS-MAX-DB-LINUX_X86_64
SAP-NetWeaver-740-SR2-Installation-Export-CD-1-3
SAP-NetWeaver-740-SR2-Installation-Export-CD-2-3
SAP-NetWeaver-740-SR2-Installation-Export-CD-3-3
```

/data/SAP_CDs is the default directory as specified in the /etc/sysconfig/sap-installation-wizard configuration file.

10. Depending on the product you are installing, one or more dialogs will prompt you to supply values for several configuration parameters for the SAP application you are installing. Supply the values as described in the documentation provided to you by SAP. Help for the configuration parameters is also available on the left side of the dialog. For more information, see Section 2.5, “Required Data for Installing”. Fill out the form (or forms), then proceed with OK.
When you are done, the SAP Installation Wizard will download additional software packages.

11. You will be asked whether to continue the installation or prepare another SAP product for installation. If you choose to prepare another SAP product, start from the beginning of this procedure.

12. *(Optional)* When installing SAP HANA on a system that is not certified for SAP HANA and does not meet the minimum hardware requirements for SAP HANA TDI (Tailored Datacenter Integration), you will be asked whether to continue. If you receive this message unexpectedly, check Section 2.1, “Hardware Requirements” and the sizing guidelines from SAP at https://service.sap.com/sizing. Otherwise, continue with Yes.

13. The following steps differ depending on the type of SAP application you are installing:

   - When installing an SAP HANA database, SAP HANA will now be installed without further question.
   - When installing an SAP NetWeaver application, the actual installation will be performed using the SAP Installer (SAPinst). After a few seconds, SAP Installer will open automatically.
Follow the SAP Installer as described in the documentation provided by SAP. Most configuration parameters are correctly filled already.

**Tip: Installation Log Files**

If the installation of the SAP application fails, refer to the installation log files. They are located in `/var/adm/autoinstall`. Failed installations are recorded in files with names ending in `.err`.

For more information about log files, see *Chapter 13, Important Log Files*.

14. The final screen is *Installation Completed*.

   To create an AutoYaST file for this installation, activate *Clone This System for AutoYaST*. The AutoYaST file will be placed in `/root/autoinst.xml`.

   Click *Finish*. 

---

*Figure 4.6: SAP Installer: Defining Parameters*
4.4 Continuing an Installation Using an Installation Profile

If you chose *Collect installation profiles but do not execute installation* during the previous run of the SAP Installation Wizard, this section will show you how to continue the installation of the selected SAP applications.

When collecting an installation profile, the SAP Installation Wizard copies product images to `/data/SAP_CDs`. It also prepares an installation environment for every product under the path `/data/SAP_INST`:

```
/data/SAP_INST/0/Instmaster
/data/SAP_INST/1/Instmaster
/data/SAP_INST/2/Instmaster
[...]
```

These files are re-used in the following. To continue the installation, follow these steps:

1. In `/etc/sysconfig/sap-installation-wizard`, set the following:
   ```
   SAP_AUTO_INSTALL="yes"
   ```

2. In the case of an SAP HANA/SAP BusinessOne installation, the SAP Installation Wizard will later use the parameters documented in the AutoYaST files in `/data/SAP_INST/number`. If you need to change any parameters, make sure to adapt the AutoYaST files at this point.

3. Open the YaST control center and start *SAP Installation Wizard*.

4. You will be asked whether to continue the pending installation. Select *Install*.

5. All further interactions happen within the SAP Installer. Follow the steps of SAP Installer as described in the documentation provided to you by SAP.

   - In the case of an SAP NetWeaver installation, all parameters of the SAP Installer will be offered again for fine-tuning.
   - In the case of an SAP HANA/SAP BusinessOne installation, the installer will not be offering to make any changes to parameters.
4.5 Partitioning for an SAP Application Without the SAP Installation Wizard

If you do not want to use the SAP Installation Wizard, you can also create the partitioning for SAP applications directly from the command line. First, find the correct partitioning file in the directory `/usr/share/YaST2/include/sap-installation-wizard/` or create an own partitioning file. For more information, see Section 2.6.2, “Partitioning for the SAP System (stage 2)”. When you have determined the correct partitioning XML file, run:

```
root # yast2 sap_create_storage ABSOLUTE_PATH_TO_PARTITIONING_FILE
```

4.6 Automated Installation of SAP Applications with AutoYaST

The SAP Installation Wizard can be used from AutoYaST to automate the installation of SAP Applications.

4.6.1 SAP HANA Installation

The following AutoYaST snippet shows how an SAP HANA or SAP TREX installation can be automated:

```
<inst>
  <products config:type="list">
    <product>
      <media config:type="list">
        <medium>
          <url>nfs://server/path1</url>
          <type>sap</type>
        </medium>
        <medium>
          <url>nfs://server/path3</url>
          <type>supplement</type>
        </medium>
      </media>
      <sapMasterPW>PASSWORD</sapMasterPW>
      <sid>SID</sid>
      <sapInstNr>INSTANCE_NUMBER</sapInstNr>
      <sapMDC>no</sapMDC>
    </product>
  </products>
</inst>
```
The `sapMDC` element is only applicable to SAP HANA.

The `sapVirtHostname` element must be specified for distributed or highly available installations.

For a full SAP HANA example, including partitioning, see `/usr/share/doc/packages/sap-installation-wizard/hana-autoyast.xml`.

### 4.6.2 SAP NetWeaver Installation

For SAP NetWeaver, the following example shows how the installation can be automated. Specifically, this example is tailored to installing ASCS Instance of an SAP NetWeaver 7.5 ABAP Server distributed system with MaxDB (product ID `NW_ABAP_ASCS:NW750.ADA.ABAP`). When installing other products based on SAP NetWeaver, not all of the following variables may be necessary or these variables might need to be replaced by others:

- The master password for the SAP NetWeaver instance: `MASTER_PASSWORD`
- The SAP Identifier (SID): `SID`
- The SAP kernel: `KERNEL`
- The SAP instance number: `INSTANCE_NUMBER`
- The ASCS virtual host name: `ASCS_VIRTUAL_HOSTNAME`
- The SCS virtual host name: `SCS_VIRTUAL_HOSTNAME`

```xml
<products config:type="list">
    <product>
        <media config:type="list">
            <medium>
                <url>nfs://SERVER/PATH1</url>

5 Setting Up an Installation Server for SAP Media Sets

Using the SAP Installation Wizard, it is possible to copy the SAP media sets from a remote server (for example, via NFS or SMB). However, using the option provided there means that you need to install the product at the same time. Additionally, it does not allow for copying all SAP media used in your organization to a single server.

However, you can easily create such a server on your own. For example, to put the SAP media sets on an NFS Server, proceed as follows:

**PROCEDURE 5.1: ADDING SAP PRODUCT INSTALLATION FILES TO AN NFS SERVER**

1. On your installation server, create the directory `/srv/www/htdocs/sap_repo`.

2. Open the file `/etc/exports` and add the following:

```
/srv/www/htdocs/sap_repo *(ro,no_root_squash,sync,no_subtree_check,insecure)
```

**Important: Executable Rights Must Be Visible**

Clients must be able to see which files are executable. Otherwise, SUSE's SAP Installation Wizard will not be able to execute the SAP Installer.

3. In `/srv/www/htdocs/sap_repo`, create a directory for every SAP medium you have. Give these directories speaking names, so you can identify them later on. For example, you could use names like `kernel`, `java`, or `hana`.

4. Copy the contents of each SAP medium to the corresponding directory with `cp -a`.

**Important: Avoid Using Windows* Operating Systems for Copying**

Using Windows operating system for copying or copying from/to Windows file systems like NTFS can break permission settings and capitalization of files and directories.

You can now install from the NFS server you set up. In the SAP Installation Wizard, specify the path this way: `server_name/srv/www/htdocs/sap_repo`. For more information about specifying the path, see *Table 4.1, “Media Source Path”*. 

SLES for SAP 12 SP4

6 Setting Up an SAP HANA Cluster

You can use a YaST wizard to set up SAP HANA or SAP S/4HANA Database Server clusters according to best practices, including SAP HANA system replication. A summary of the setup options is given in Section 1.1.3, “Simplified SAP HANA System Replication Setup”.

The following Best Practices from the SUSE Linux Enterprise Server for SAP Applications Resource Library (https://www.suse.com/products/sles-for-sap/resource-library/) contain setup instructions:

- Performance-optimized scenario and multi-tier/chained scenario: Setting up a SAP HANA SR Performance Optimized Infrastructure
- Cost-optimized scenario: Setting up a SAP HANA SR Cost Optimized Infrastructure

⚠️ Important: Wizard Can Only Be Used for Initial Configuration

The YaST wizard described in the following can only be used for the initial cluster configuration.

To reconfigure a cluster, use the separate YaST module Cluster (available from package yast2-cluster). For more information about its usage, see Administration Guide, Part “Installation, Setup and Upgrade”, Chapter “Using the YaST Cluster Module” at https://www.suse.com/documentation/sle-ha-12/.

⚠️ Important: Not Suitable for Cloud Deployments

The instructions in the following sections are suitable for deployments on physical machines. They are not intended for cloud-based deployments.

6.1 Prerequisites

The following procedure has prerequisites:

- Two machines which both have an SAP HANA installation created by the SAP Installation Wizard or SAP HANA Application Lifecycle Management. Both machines need to be on the same L2 network (subnet).
In the case of a multi-tier/chained scenario, there must also be a third machine elsewhere.

- The machines are not yet set up as a high-availability cluster.
- openSSH is running on both machines and the nodes can reach each other via SSH. However, if that has not already happened, the wizard will perform the SSH key exchange itself. For more information about SSH, see Security Guide, Part “Network Security”, Chapter “SSH: Secure Network Operations” at https://www.suse.com/documentation/sles-12/.
- A disk device that is available to both nodes under the same path for SBD. It must not use host-based RAID, cLVM2 or reside on a DRBD instance. The device can have a small size, for example, 100 MB.
- You have created either:
  - A key in the SAP HANA Secure User Store on the primary node
  - An initial SAP HANA backup on the primary node
- The package `yast2-sap-ha` is installed on both the primary and the secondary node.
- HANA-Firewall is set up on both computers with the rules `HANA_HIGH_AVAILABILITY` and `HANA_SYSTEM_REPLICATION` on all relevant network interfaces.
  For information about setting up HANA-Firewall, see Section 8.2, “Configuring HANA-Firewall”.
- **Cost-optimized scenario only**: The secondary node has a second SAP HANA installation. The database may be running but will be stopped automatically by the wizard.
- **Cost-optimized scenario only**: For the non-production SAP HANA instance, you have created an SAP HANA Secure User Store key `QASSAPDBCTRL` for monitoring purposes. For more information, see SAP HANA SR Cost Optimized Scenario, Chapter “Installing the SAP HANA Databases on both cluster nodes”, Section “Postinstallation configuration”, Section “Install the non-productive SAP HANA database (QAS)” at https://www.suse.com/products/sles-for-sap/resource-library/.

## 6.2 Setup

The following procedure needs to be executed on the primary node (also called the “master”). Before proceeding, make sure the prerequisites listed in Section 6.1, “Prerequisites” are fulfilled.
1. Open the YaST control center. In it, click HA Setup for SAP Products in the category High Availability.

2. If an SAP HANA instance has been detected, you can choose between the scale-up scenarios Performance-optimized, Cost-optimized, or Chained (multi-tier). For information about these scale-up scenarios, see Section 1.1.3, “Simplified SAP HANA System Replication Setup”. Continue with Next.

3. This step of the wizard presents a list of prerequisites for the chosen scale-up scenario. These prerequisites are the same as those presented in Section 6.1, “Prerequisites”. Continue with Next.

4. The next step lets you configure the communication layer of your cluster.

   - Provide a name for the cluster.
   - The default transport mode Unicast is usually appropriate.
   - Under Number of rings, a single communication ring usually suffices. For redundancy, it is often better to use network interface bonding instead of multiple communication rings. For more information, see Administration Guide, Part “Configuration and Administration”, Chapter “Network Device Bonding” at https://www.suse.com/documentation/sle-ha-12/.

   - From the list of communication rings, configure each enabled ring. To do so, click Edit selected, then select a network mask (IP address) and a port (Port number) to communicate over.
Finish with OK.

- Additionally, decide whether to enable the configuration synchronization service Csync2 and Corosync secure authentication using HMAC/SHA1. For more information about Csync2, see Administration Guide Part “Installation, Setup and Upgrade”, Chapter “Using the YaST Cluster Module”, Section “Transferring the Configuration to All Nodes” at https://www.suse.com/documentation/sle-ha-12/.

Proceed with Next.

5. The wizard will now check whether it can connect to the secondary machine using SSH. If it can, it will ask for the root password to the machine. Enter the root password.
   The next time, the primary machine needs to connect to the secondary machine, it will connect using an SSH certificate instead of a password.

6. For both machines, set up the host names and IP address (for each ring). Host names chosen here are independent from the virtual host names chosen in SAP HANA. However, to avoid issues with SAP HANA, host names must not include hyphen characters (-).
If this has not already been done before, such as during the initial installation of SAP HANA, host names of all cluster servers must now be added to the file `/etc/hosts`. For this purpose, activate Append to `/etc/hosts`. Proceed with Next.

7. If NTP is not yet set up, do so. This avoids the two machines from running into issues because of time differences.
   a. Click Reconfigure.
   b. On the tab General Settings, activate Now and on Boot.
   c. Add a time server by clicking Add. Click Server and Next. Then specify the IP address of a time server outside of the cluster. Test the connection to the server by clicking Test.
      To use a public time server, click Select > Public server and select a time server. Finish with OK.
      Proceed with OK.
   d. On the tab Security Settings, activate Open Port in Firewall.
   e. Proceed with Next.

8. In the next step, choose fencing options. The YaST wizard only supports the fencing mechanism SBD (STONITH block device). To avoid split-brain situations, SBD uses a disk device which stores cluster state.
   The chosen disk must be available from all machines in the cluster under the same path.
   Ideally, use either by-uuid or by-path for identification.
   The disk must not use host-based RAID, cLVM2 or reside on a DRBD instance. The device can have a small size, for example, 100 MB.

   ⚠️ Warning: Data on Device Will Be Lost
   All data on the chosen SBD device or devices will be deleted.

   To define a device to use, click Add, then choose an identification method such as by-uuid and select the appropriate device. Click OK.
   To define additional SBD command-line parameters, add them to SBD options.
   If your machines reboot particularly fast, activate Delay SBD start.
For more information about fencing, see the Administration Guide at https://www.suse.com/documentation/sle-ha-12/.
Proceed with Next.

9. The following page allows configuring watchdogs which protect against the failure of the SBD daemon itself and force a reboot of the machine in such a case.
It also lists watchdogs already configured using YaST and watchdogs that are currently loaded (as detected by `lsmod`).
To configure a watchdog, use Add. Then choose the correct watchdog for your hardware and leave the dialog with OK.
For testing, you can use the watchdog `softdog`. However, we highly recommend using a hardware watchdog in production environments instead of `softdog`. For more information about selecting watchdogs, see Administration Guide, Part “Storage and Data Replication”, Chapter “Storage Protection”, Section “Conceptual Overview”, Section “Setting Up Storage-based Protection”, Section “Setting up the Watchdog” at https://www.suse.com/documentation/sle-ha-12/.
Proceed with Next.

10. Set up the parameters for your SAP HANA installation or installations. If you have selected the cost-optimized scenario, additionally, fill out details related to the non-production SAP HANA instance.

Production SAP HANA Instance

- Make sure that the System ID and Instance number match those of your SAP HANA configuration.

- Replication mode and Operation mode usually do not need to be changed.
  For more information about these parameters, see the HANA Administration Guide provided to you by SAP.

- Under Virtual IP address, specify a virtual IP address for the primary SAP HANA instance. Under Virtual IP Mask, set the length of the subnetwork mask in CIDR format to be applied to the Virtual IP address.

- Prefer site takeover defines whether the secondary instance should take over the job of the primary instance automatically (true). Alternatively, the cluster will restart SAP HANA on the primary machine.
• **Automatic registration** determines whether primary and secondary machine should switch roles after a takeover.

• Specify the site names for the production SAP HANA instance on the two nodes in *Site name 1* and *Site name 2*.

• Having a backup of the database is a precondition for setting up SAP HANA replication.
  If you have not previously created a backup, activate *Create initial backup*. Under *Backup settings*, configure the *File name* and the *Secure store key* for the backup. The key in the SAP HANA Secure User Store on the primary node must have been created before starting the wizard.
  For more information, see the documentation provided to you by SAP.

• **Cost-optimized scenario only:** Within *Production system constraints*, configure how the production instance of SAP HANA should behave while inactive on the secondary node.
  Setting the *Global allocation limit* allows directly limiting memory usage. Activating *Preload column tables* will increase memory usage.
  For information about the necessary global allocation limit, see documentation provided to you by SAP such as *How to Perform System Replication for SAP HANA* at https://archive.sap.com/documents/docs/DOC-47702.

  **Cost-optimized Scenario Only: Non-production SAP HANA Instance**

• Make sure that the *System ID* and *Instance number* match those of your non-production SAP HANA instance.
  These parameters are needed to allow monitoring the status of the non-production SAP HANA instance using the SAPInstance resource agent.

• Generate a hook script for stopping the non-production instance and starting the production instance and removing the constraints on the production system.
  The script is written in Python 2 and can be modified as necessary later.
  Click *Hook script* and then set up the correct user name and password for the database. Then click *OK*.
  You can now manually verify and change the details of the generated hook script. When you are done, click *OK* to save the hook script at `/hana/shared/SID/srHook`. 
Warning: Passwords Stored in Plain Text

By default, the hook script stores all credentials in plain text. To improve security, modify the script yourself.

Proceed with Next.

FIGURE 6.1: SAP HANA OPTIONS (COST-OPTIMIZED SCENARIO)

11. On the page High-Availability Configuration Overview, check that the setup is correct. To change any of the configuration details, return to the appropriate wizard page by clicking one of the underlined headlines. Proceed with Install.

12. When asked whether to install additional software, confirm with Install.

13. After the setup is done, there is a screen showing a log of the cluster setup. To be able to reuse the configuration file for an unattended installation, click Save configuration. (For more details about unattended cluster installations, see Section 6.3, “Unattended Installation of Cluster Servers”.) To close the dialog, click Finish.

14. **Multi-tier/chain scenario only:** Using the administrative user account for the production SAP HANA instance, register the out-of-cluster node for system replication:

```
SIDadm > hdbnsutil -sr_register --remoteHost=SECONDARY_HOST_NAME
```
6.3 Unattended Installation of Cluster Servers

On bare-metal servers, you can run the YaST module HA Setup for SAP Products in an unattended mode to speed up the time it takes to configure additional servers with the same configuration. As a prerequisite, you need a configuration file from a previous run of the YaST wizard HA Setup for SAP Products.

1. Copy the configuration file to the target machine.
2. Validate the configuration file:

   ```
   root # yast2 sap_ha readconfig CONFIGURATION_FILE_PATH
   ```
3. Import, validate, and install the cluster unattendedly:

   ```
   root # yast2 sap_ha readconfig CONFIGURATION_FILE_PATH unattended
   ```

6.4 Using Hawk

After you have set up the cluster using the wizard, you can open Hawk. directly from the last screen of the HA Setup for SAP Products wizard.

To revisit Hawk, open a browser and as the URL, enter the IP address or host name of any cluster node running the Hawk Web service. Alternatively, enter the virtual IP address you configured in Section 6.2, “Setup”.

```
https://HAWKSERVER:7630/
```

On the Hawk login screen, use the following login credentials:

- **Username**: hacluster
- **Password**: linux
Important: Secure Password

Replace the default password with a secure one as soon as possible:

```
root # passwd hacluster
```

For more information about Hawk, see Administration Guide, Part “Configuration and Administration”, Chapter “Configuring and Managing Cluster Resources with Hawk” (https://www.suse.com/documentation/sle-ha-12/).
This chapter presents information about tuning SLES for SAP to work optimally with SAP applications.

Note: Choosing between sapconf and saptune

On SUSE Linux Enterprise Server for SAP Applications you have the choice between sapconf and saptune. However, saptune is the more elaborate tool that offers more features.

7.1 Kernel: Page-Cache Limit

Problem
The kernel swaps out rarely accessed memory pages to use freed memory pages as cache to speed up file system operations, for example during backup operations. SAP NetWeaver and SAP HANA use large amounts of memory for accelerated access to business data. Parts of this memory are rarely accessed. When a user request needs to access paged-out memory, the response time is poor. It is even worse when an SAP application running on Java incurs a Java garbage collection: The system starts heavy page-in (disk I/O) activity and has a poor response time for an extended period of time.

Solution
SUSE Linux Enterprise Server for SAP Applications includes a kernel tuning option that allows the system administrator to limit the amount of page cache that the kernel uses when there is competition between application memory and page cache. This option tells the kernel that when the page cache is filled to the configured limit, application memory is more important and should thus not be paged out. No pages will be paged out if the memory footprint of the workload plus the configured page-cache limit do not exceed the amount of physical RAM in the system.

These kernel options are available for configuration:

- `vm.pagecache_limit_mb (/proc/sys/vm/pagecache_limit_mb)`
- `vm.pagecache_limit_ignore_dirty (/proc/sys/vm/pagecache_limit_ignore_dirty)`
Tip: Use sapconf to Configure Parameters

The parameters `vm.pagecache_limit_mb` and `vm.pagecache_limit_ignore_dirty` are also configured by the `tuned` profiles delivered with `sapconf`.

For more information, see Section 7.2, “Tuning Systems with sapconf”.

Important: The Following Are Example Values

The values reproduced in Example 7.1, “Permanently Setting the Page-Cache Limit” are example values only. Do not set the following parameters on a productive system without first trying and calibrating them on a non-productive system.

If your system does not exhibit page-cache limit issues under the workloads it is running, there is no need to adjust these parameters.

For more information, see SAP Note 1557506: Linux Paging Improvements (https://launchpad.support.sap.com/#/notes/1557506).

Example 7.1: Permanently Setting the Page-Cache Limit

For permanent use, add both parameters to `/etc/sysctl.conf`, for example:

```
vm.pagecache_limit_mb = 1024
vm.pagecache_limit_ignore_dirty = 2
```

7.2 Tuning Systems with sapconf

The package `sapconf` contains the `tuned` profile `sap-netweaver`. This single tuning profile sets recommended parameters for SAP applications, in particular SAP NetWeaver, SAP HANA, and SAP HANA-based applications.

`sapconf` consists of two primary parts:

- A `systemd` service that ensures `tuned` and related services are running and the `sap-netweaver` profile is applied.

- The `tuned` profile `sap-netweaver` that applies configured `sapconf` tuning parameters using a script and configuration files.

(The profile `sap-hana` is currently identical to `sap-netweaver`. `sapconf` additionally includes the profiles `sap-ase` and `sap-bobj` which are currently not recommended for use.)
To use `sapconf`, install the package `sapconf` on your system.

**Note: sapconf Utility**

The command-line utility `sapconf` is still available in SUSE Linux Enterprise Server for SAP Applications 12 SP4. However, it is no longer the preferred utility to control `sapconf`.

Starting with SUSE Linux Enterprise Server for SAP Applications 15, the utility `sapconf` is not included in the package `sapconf` anymore.

**Note: Unified Profiles in SUSE Linux Enterprise Server for SAP Applications 15**

In SUSE Linux Enterprise Server for SAP Applications 15 and up, only a single `tuned` profile, `sapconf`, is shipped. It is equivalent to the profiles `sap-hana/sap-netweaver` (both profiles are identical) that are shipped with `sapconf` in SUSE Linux Enterprise Server for SAP Applications 12 SP4.

7.2.1 **Enabling and Disabling sapconf and Viewing Its Status**

After the installation of `sapconf`, `tuned` is enabled and the `sap-netweaver` profile is activated. However, if another `tuned` profile is already enabled, `sapconf` will not enable its own `tuned` profile. If you previously made other changes to system tuning, these may be overridden by the profile of `sapconf`.

To make sure `sapconf` applies all tuning parameters, reboot the machine after installation.

You can inspect or change the status of `sapconf` as described in the following:

- To see the status of the service `sapconf`:

  ```
  root # systemctl status sapconf
  ```

  The service should be displayed as `active (exited)`, as it is only responsible for starting `tuned` and will exit afterward.

- To start the service `sapconf` and with it the service `tuned`:

  ```
  root # systemctl start sapconf
  ```
• Should `sapconf` be disabled, enable and start it with:

```bash
root # systemctl enable --now sapconf
```

• To stop the service `sapconf` and with it the service `tuned`:

```bash
root # systemctl stop sapconf
```

As `tuned` is also terminated at that point, the vast majority of optimizations which do not require a system reboot to disable are disabled immediately.

• To disable `sapconf`, use:

```bash
root # systemctl disable sapconf
```

If you have not specifically enabled any of the services that `sapconf` depends on yourself, this will also disable most tuning parameters and all services used by `sapconf`.

Similarly, you can inspect and change the status of the underlying service `tuned`:

• To see the status of the service `tuned`:

```bash
root # systemctl status tuned
```

• To see which `tuned` profile is currently in use:

```bash
root # tuned-adm active
```

If this command does not return the name of the currently active profile as `sap-netweaver`, enable that profile:

```bash
root # tuned-adm profile sap-netweaver
```
Tip: Additional Services that sapconf Relies On

In addition to the `sapconf` service itself and the `tuned` service, `sapconf` also relies on the following two services:

- `sysstat` collects data on system activity.
- `uuid` which generates time-based UUIDs that are guaranteed to be unique even in settings where many processor cores are involved. This is necessary for SAP applications.

7.2.2 Configuring sapconf

In general, the default configuration of `sapconf` already uses the parameter values recommended by SAP. However, if you have special needs, you can configure the tool to better suit those. The configuration of `sapconf` is split in two parts that can be configured in different ways:

`/usr/lib/tuned/sap-netweaver/tuned.conf`

This file contains basic parameters. It also calls the `script.sh` from the same directory. To configure parameters from this file, copy it to the custom profile directory of `tuned` under `/etc/tuned` first and then change values in it. If you change the file in place instead, you will lose the changes you make on the next update of the `sapconf` package.

Configure the file as described in the following:

PROCEDURE 7.1:

1. Create a new custom `tuned` profile directory and copy the file `tuned.conf`:

```bash
root # mkdir /etc/tuned/sap-netweaver
root # cp /usr/lib/tuned/sap-netweaver/tuned.conf /etc/tuned/sap-netweaver/
```

2. Within the newly copied `tuned.conf`, fix the reference to `script.sh` to use an absolute path that points to the script from the original profile:

```bash
script = /usr/lib/tuned/sap-netweaver/script.sh
```

Do not instead copy `script.sh`, as that provokes update compatibility issues for `sapconf`.

3. Edit the parameters in `/etc/tuned/sap-netweaver/tuned.conf`.
After each update to `sapconf`, make sure to compare the contents of the original and the custom `tuned.conf`.

Log messages related to this file are written to `/var/log/tuned/tuned.log`.

`/etc/sysconfig/sapconf`

This file contains most parameters of `sapconf`. The parameters from this file are applied using the aforementioned script `/usr/lib/tuned/sap-netweaver/script.sh`.

This file can be edited directly. All parameters in this file are explained by means of comments and references to SAP Notes which can be viewed at [https://launchpad.support.sap.com/](https://launchpad.support.sap.com/).

When `sapconf` is updated, all customized parameters from this file will be preserved as much as possible. However, sometimes parameters cannot be transferred cleanly to the new configuration file. Therefore, after updating it is advisable to check the difference between the previous custom configuration which during the update is moved to `/etc/sysconfig/sapconf.rpmsave` and the new version at `/etc/sysconfig/sapconf`.

Log messages related to this file are written to `/var/log/sapconf.log`.

When editing either of these files, you will find that some values are commented by means of a `#` character at the beginning of the line. This means that while the parameter is relevant for tuning, there is no suitable default for it.

Conversely, you can add `#` characters to the beginning of the line to comment specific parameters. However, you should avoid this praxis, as it can lead to `sapconf` not properly applying the profile.

To apply edited configuration, restart `sapconf`:

```bash
root # systemctl restart sapconf
```

Confirming that a certain parameter value was applied correctly works differently for different parameters. Hence, the following serves as an example only:

**EXAMPLE 7.2: CHECKING PARAMETERS**

To confirm that the setting for `TCP_SLOW_START` was applied, do the following:

- View the log file of `sapconf` to see whether it applied the value. Within `/var/log/sapconf.log`, check for a line containing this text:

```text
Change net.ipv4.tcp_slow_start_after_idle from 1 to 0
```
Alternatively, the parameter may have already been set correctly before `sapconf` was started. In this case, `sapconf` will not change its value:

```
Leaving net.ipv4.tcp_slow_start_after_idle unchanged at 1
```

- The underlying option behind `TCP_SLOW_START` can be manually configured at `/proc/sys/net.ipv4.tcp_slow_start_after_idle`. To check its actual current value, use:

```
root # sysctl net.ipv4.tcp_slow_start_after_idle
```

### 7.2.3 Removing sapconf

To remove `sapconf` from a system, uninstall its package with:

```
root # zypper rm sapconf
```

Note that when doing this, dependencies of `sapconf` will remain installed. However, the services `sysstat` and `tuned` will go into a disabled state. If either is still relevant to you, make sure to enable it again.

Certain parameters and files are not removed when `sapconf` is uninstalled. For more information, see the man page `man 7 sapconf`, section `PACKAGE REQUIREMENTS`.

### 7.2.4 For More Information

The following man pages provide additional information about `sapconf`:

- High-level overview of tuning parameters used by `sapconf`: `man 7 tuned-profiles-sapconf`

- Detailed description of all tuning parameters set by `sapconf`: `man 5 sapconf`

- Information about configuring and customizing the `sapconf` profile: `man 7 sapconf`

Also see the blog series detailing the updated version of `sapconf` at [https://www.suse.com/c/a-new-sapconf-is-available/](https://www.suse.com/c/a-new-sapconf-is-available/).
7.3 Tuning Systems with **saptune**

Using **saptune**, you can tune a system for SAP NetWeaver, SAP HANA/SAP BusinessObjects, and SAP S/4HANA applications. This method relies on the system tuning service **tuned**.

If you used the SAP Installation Wizard to install an SAP application, **tuned** is usually already active and configured with a profile for the application you installed.

If you did not use the SAP Installation Wizard to install an SAP application, make sure that the packages **tuned** and **saptune** are installed on your system.

### 7.3.1 Enabling **saptune** to Tune for an SAP Application

1. To tune a system, first find a tuning solutions. To find the appropriate solution, use:

   ```bash
tux > saptune solution list
   ``

   **saptune** knows the following tuning solutions (group of SAP notes):

   - **BOBJ**. Solution for running SAP BusinessObjects.
   - **HANA**. Solution for running a SAP HANA database.
   - **MAXDB**. Solution for running a SAP MaxDB database.
   - **NETWEAVER**. Solution for running SAP NetWeaver application servers.
   - **S4HANA-APPSERVER**. Solution for running SAP S/4HANA application servers (identical to SAP NetWeaver solution).
   - **S4HANA-APP+DB**. Solution for running both SAP S/4HANA application servers and SAP HANA on the same host (identical to SAP NetWeaver + SAP HANA solution).
   - **S4HANA-DBSERVER**. Solution for running the SAP HANA database of an SAP S/4HANA installation (identical to SAP HANA solution)
   - **SAP-ASE**. Solution for running an SAP Adaptive Server Enterprise database.

   Alternatively, you can tune the computer according to recommendations from specific SAP Notes. A list of notes that you can tune for is available via:

   ```bash
   root # saptune note list
   ```
2.  To set up *saptune* with a preconfigured solution, use:

```
root # saptune solution apply SOLUTION
```

To set up *saptune* for the recommendations of a specific SAP Note, use:

```
root # saptune note apply NOTE
```

**Note: Combining Optimizations**

You can combine solutions and notes. However, you can only have one solution. In rare cases, notes can have conflicting options or parameters. To avoid conflicts, order your notes, keeping in mind that the last note always overrides the conflicting options or parameters in previous notes.

3.  To start *saptune* and enable it at boot, make sure to run the following command:

```
root # saptune daemon start
```

In the background, *saptune* applies a *tuned* profile also named *saptune* that is dynamically customized according to selected “solutions” and “notes”. Using *tuned-adm list*, you can also see this profile.

7.3.2  Customizing a SAP Note

Every SAP note can be configured freely with:

```
root # saptune note customise
```

The command includes changing a value or disabling a parameter.

7.3.3  Creating a new SAP Note

It is possible to create a new SAP note with:

```
root # saptune note create
```

All features of *saptune* are available.
7.3.4 Showing the Configuration of a SAP Note

The shipped configuration of a note can be listed with:

```
root # saptune note show
```

7.3.5 Verifying a SAP Note or a SAP Solution

The command `saptune note|solution verify [note]` lists for each active or requested note: the parameter name, the expected value (default), a configured override (done by a `saptune customise`) the current system value and if the current state is compliant to the SAP recommendation or not.

7.3.6 Simulating the Apply of a SAP Note or a SAP Solution

To show each parameter, use:

```
root # saptune note|solution simulate
```

It lists the current system value and the expected values (default and override is listed too).

7.3.7 Disabling `saptune`

To disable `saptune` and to stop and disable `tuned` run:

```
root # saptune daemon stop
```

7.3.8 Tuning Kernel Parameters Manually Using `sysctl`

In addition to or instead of tuning kernel parameters using `saptune`, you can also use `sysctl` to make manual adjustments to kernel parameters. However, such changes using `sysctl` do not persist across reboots by default. To make them persist across reboots, add them to the file `/etc/sysctl.conf` (or another configuration file read by `sysctl`).
If you plan to configure sysctl parameters for your SAP system, consider to use `saptune` as a central instance for managing your system configuration.

For more information about `sysctl`, see the man pages `sysctl(8)`, `sysctl.conf(5)`, and `sysctl.d(5)`.

7.3.9 For More Information

See the following man pages:

- `man 8 saptune`
- `man 8 saptune_v1`
- `man 8 saptune_v2`
- `man 8 saptune-migrate`
- `man 8 saptune-note`

Also see the project home page [https://github.com/SUSE/saptune/](https://github.com/SUSE/saptune/).

7.4 Tuning Kernel Parameters Manually Using `sysctl`

In addition to or instead of tuning kernel parameters using `sapconf/saptune`, you can also use `sysctl` to make manual adjustments to kernel parameters. However, such changes using `sysctl` do not persist across reboots by default. To make them persist across reboots, add them to one of the configuration files read by `sysctl`.

For more information about `sysctl`, see the man pages `sysctl(8)`, `sysctl.conf(5)`, and `sysctl.d(5)`.
8 Firewalling

This chapter presents information about restricting access to the system using firewalling and encryption and gives information about connecting to the system remotely.

8.1 Configuring SuSEFirewall2

By default, the installation workflow of SUSE Linux Enterprise Server for SAP Applications enables SuSEFirewall2. The firewall needs to be manually configured to allow network access for the following:

- SAP application
- Database (see the documentation of your database vendor; for SAP HANA, see Section 8.2, “Configuring HANA-Firewall”)

Additionally, open the ports 1128 (TCP) and 1129 (UDP).

SAP applications require many open ports and port ranges in the firewall. The exact numbers depend on the selected instance. For more information, see the documentation provided to you by SAP.

8.2 Configuring HANA-Firewall

To simplify setting up a firewall for SAP HANA, install the package HANA-Firewall. HANA-Firewall adds rule sets to your existing SuSEFirewall2 configuration.

HANA-Firewall consists of the following parts:

- **YaST Module SAP HANA Firewall.** Allows configuring, applying, and reverting firewall rules for SAP HANA from a graphical user interface.

- **Command-Line Utility hana-firewall.** Allows applying and reverting the configured firewall rules for SAP HANA.
  
  If you prefer, you can configure the rule sets using the configuration file at /etc/sysconfig/hana-firewall instead of using YaST.

- **Service hana-firewall.** Ensures that configured firewall rules for SAP HANA are kept.
Important: SAP HANA MDC Databases

For multi-tenant SAP HANA (MDC) databases, determining the port numbers that need to be opened is not yet possible automatically. If you are working with a multi-tenant SAP HANA database system, before you use YaST, run a script on the command line to create a new service definition:

```
root # cd /etc/hana-firewall.d
root # ./create_new_service
```

You need to switch to the directory `/etc/hana-firewall.d`, otherwise the rule file for the new service will be created in a place where it cannot be used.

The script will ask several questions: Importantly, it will ask for TCP and UDP port ranges that need to be opened.

Note: Install HANA-Firewall Packages

Before continuing, make sure that the packages `HANA-Firewall` and `yast2-hana-firewall` are installed.

PROCEDURE 8.1: USING HANA-FIREWALL

1. Make sure the SAP HANA databases for which you want to configure the firewall are correctly installed.

2. To open the appropriate YaST module, select Applications > YaST, Security and Users > SAP HANA Firewall.

3. When you open this YaST module, it will create a configuration proposal based on the number of installed SAP HANA instances. Choose whether you want to accept the proposal using Yes or No.

Important: Narrow Down Settings from Proposal

The proposed settings allow all detected SAP HANA instances on all detected network interfaces. Narrow down the proposal to secure the system further.

5. Choose a network interface under Allowed Services on Network Interface.

6. Allow network services by selecting them in the list box on the left and clicking →. Remove services by selecting them in the list box on the right and clicking ←.

To add services other than the preconfigured ones, add them using the following notation:

```
SERVICE_NAME:CIDR_NOTATION
```

For more information about the CIDR notation, see https://en.wikipedia.org/wiki/Classless_Inter-Domain_Routing. To find out which services are available on your system, use `getent services`.

7. Repeat from Step 5 for all network interfaces.

8. When you are done, click OK.

The firewall rules from HANA-Firewall will now be compiled and applied. Then, the service `hana-firewall` will be restarted.

9. Finally, check whether HANA-Firewall was enabled correctly:

```
root # hana-firewall status
HANA firewall is active. Everything is OK.
```
Tip: Checking Which Firewall Rules Are Enabled

Gaining an overview of which firewall rules are enabled in the current configuration of the script is possible using the command line:

```
root # hana-firewall dry-run
```

For more information, see the man page of `hana-firewall`.

8.3 SAProuter Integration

The SAProuter software from SAP allows proxying network traffic between different SAP systems or between an SAP system and outside networks. SUSE Linux Enterprise Server for SAP Applications now provides integration for SAProuter into systemd. This means, SAProuter will be started and stopped properly with the operating system and can be controlled using `systemctl`.

Before you can use this functionality, make sure the following has been installed, in this order:

- An SAP application that includes SAProuter
- The SAProuter systemd integration, packaged as `systemd-saprouter`

If you got the order of applications to install wrong initially, reinstall `systemd-saprouter`.

To control SAProuter with `systemctl`, use:

- Enabling the SAProuter Service: `systemctl enable saprouter`
- Starting the SAProuter Service: `systemctl start saprouter`
- Showing the Status of SAProuter Service: `systemctl status saprouter`
- Stopping the SAProuter Service: `systemctl stop saprouter`
- Disabling the SAProuter Service: `systemctl disable saprouter`
9 Encrypting Directories Using cryptctl

**cryptctl** consists of two components:

- A client is a machine that has one or more encrypted partitions but does not permanently store the necessary key to decrypt those partitions. For example, clients can be cloud or otherwise hosted machines.

- The server holds encryption keys that can be requested by clients to unlock encrypted partitions.
  You can also set up the **cryptctl** server to store encryption keys on a KMIP 1.3-compatible (Key Management Interoperability Protocol) server. In that case, the **cryptctl** server will not store the encryption keys of clients and is dependent upon the KMIP-compatible server to provide these.

⚠️ **Warning: cryptctl Server Maintenance**

Since the **cryptctl** server manages timeouts for the encrypted disks and, depending on the configuration, can also hold encryption keys, it should be under your direct control and managed only by trusted personnel.

Additionally, it should be backed up regularly. Losing the server's data means losing access to encrypted partitions on the clients.

To handle encryption, **cryptctl** uses LUKS with aes-xts-256 encryption and 512-bit keys. Encryption keys are transferred using TLS with certificate verification.
Note: Install `cryptctl`

Before continuing, make sure the package `cryptctl` is installed on all machines you intend to set up as servers or clients.

### 9.1 Setting Up a `cryptctl` Server

Before you can define machine as a `cryptctl` client, you need to set up a machine as a `cryptctl` server.

Before beginning, choose whether to use a self-signed certificate to secure communication between the server and clients. If not, generate a TLS certificate for the server and have it signed by a certificate authority.

Additionally, you can have clients authenticate to the server using certificates signed by a certificate authority. To use this extra security measure, make sure to have a CA certificate at hand before starting this procedure.

1. As `root`, run:

   ```
   root # cryptctl init-server
   ```

2. Answer each of the following prompts and press `Enter` after every answer. If there is a default answer, it is shown in square brackets at the end of the prompt.
a. Choose a password with at least 10 characters and confirm it. This password assumes the role of a master password, able to unlock all partitions that are registered on the server.

b. Specify the path to a PEM-encoded TLS certificate or certificate chain file or leave the field empty to create a self-signed certificate. If you specify a path, use an absolute path.

c. If you want the server to be identified by a host name other than the default shown, specify a host name. cryptctl will then generate certificates which include the host name.

d. Specify the IP address that belongs to the network interface that you want to listen on for decryption requests from the clients, then set a port number (the default is port 3737). The default IP address setting, 0.0.0.0 means that cryptctl will listen on all network interfaces for client requests using IPv4.

e. Specify a directory on the server that will hold the decryption keys for clients.

f. Specify whether clients need to authenticate to the server using a TLS certificate. If you choose No, this means that clients authenticate using disk UUIDs only. (However, communication will be encrypted using the server certificate in any case.) If you choose Yes, pick a PEM-encoded certificate authority to use for signing client certificates.

g. Specify whether to use a KMIP 1.3-compatible server (or multiple such servers) to store encryption keys of clients. If you choose this option, provide the host names and ports for one or multiple KMIP-compatible servers. Additionally, provide a user name, password, a CA certificate for the KMIP server, and a client identity certificate for the cryptctl server.

⚠ Important: No Easy Reconfiguration of KMIP Setting

The setting to use a KMIP server cannot easily be changed later. To change this setting, both the cryptctl server and its clients need to be configured afresh.
h. Finally, configure an SMTP server for e-mail notifications for encryption and decryption requests or leave the prompt empty to skip setting up e-mail notifications.

Note: Password-Protected Servers

\texttt{cryptctl} currently cannot send e-mail using authentication-protected SMTP servers. If that is necessary, set up a local SMTP proxy.

i. When asked whether to start the \texttt{cryptctl} server, enter \texttt{y}.

3. To check the status of the service \texttt{cryptctl-server}, use:

\begin{verbatim}
root # systemctl status cryptctl-server
\end{verbatim}

To reconfigure the server later, do either of the following:

- Run the command \texttt{cryptctl init-server} again. \texttt{cryptctl} will then propose the existing settings as the defaults, so that you only need to specify values that you want to change.

- Make changes directly in the configuration file \texttt{/etc/sysconfig/cryptctl-server}. However, to avoid issues, do not change the settings \texttt{AUTH_PASSWORD_HASH} and \texttt{AUTH_PASSWORD_SALT} manually. The values of these options need to be calculated correctly.

9.2 Setting Up a \texttt{cryptctl} Client

The following interactive setup of \texttt{cryptctl} is currently the only setup method.

Make sure the following preconditions are fulfilled:

- A \texttt{cryptctl} server is available over the network.

- There is a directory to encrypt.

- The client machine has an empty partition available that is large enough to fit the directory to encrypt.
- When using a self-signed certificate, the certificate (*.crt file) generated on the server is available locally on the client. Otherwise, the certificate authority of the server certificate must be trusted by the client.

- If you set up the server to require clients to authenticate using a client certificate, prepare a TLS certificate for the client which is signed by the CA certificate you chose for the server.

1. As root, run:

```
root # cryptctl encrypt
```

2. Answer each of the following prompts and press [Enter] after every answer. If there is a default answer, it is shown in square brackets at the end of the prompt.

   a. Specify the host name and port to connect to on the `cryptctl` server.

   b. If you configured the server to have clients authenticate to it using a TLS certificate, specify a certificate and a key file for the client. The client certificate must be signed by the certificate authority chosen when setting up the server.

   c. Specify the absolute path to the server certificate (the *.crt file).

   d. Enter the encryption password that you specified when setting up the server.

   e. Specify the path to the directory to encrypt. Specify the path to the empty partition that will contain the encrypted content of the directory.

   f. Specify the number of machines that are allowed to decrypt the partition simultaneously.

   Then specify the timeout in seconds before additional machines are allowed to decrypt the partition after the last vital sign was received from the client or clients. When a machine unexpectedly stops working and then reboots, it needs to be able to unlock its partitions again. That means, this timeout should be set to a time slightly shorter than the reboot time of the client.

   **Important: Timeout Length**

   If the time is set too long, the machine cannot decrypt encrypted partitions on the first try. `cryptctl` will then continue to periodically check whether the encryption key has become available. However, this will introduce a delay.
If the timeout is set too short, machines with a copy of the encrypted partition have an increased chance of unlocking the partition first.

3. To start encryption, enter `yes`. 
   `cryptctl` will now encrypt the specified directory to the previously empty partition and then mount the newly encrypted partition. The file system type will be of the same type as the original unencrypted file system.
   Before creating the encrypted partition, `cryptctl` moves the unencrypted content of the original directory to a location prefixed with `cryptctl-moved-`.

4. To check that the directory is indeed mounted correctly, use:
   ```bash
   tux > lsblk -o NAME,MOUNTPOINT,UUID
   NAME                        MOUNTPOINT          UUID
   [...]                        
   sdc └─sdc1
       └─cryptctl-unlocked-sdc1 /secret-partition
   PARTITION_UUID
   └─cryptctl-unlocked-sdc1
   UNLOCKED_UUID
   
   cryptctl identifies the encrypted partition by its UUID. In the previous example, that is the UUID displayed next to `sdc1`.
   On the server, you can check whether the directory was decrypted using `cryptctl`:
   ```bash
   root # cryptctl list-keys
   2016/10/10 10:00:00 ReloadDB: successfully loaded database of 1 records
   Total: 1 records (date and time are in zone EDT)
   Used By      When                  UUID  Max.Users  Num.Users  Mount Point
   IP_ADDRESS   2016-10-10 10:00:00  UUID 1          1          /secret-partition
   
   Verify that the UUID shown is that of the previously encrypted partition.

5. After verifying that the encrypted partition works, delete the unencrypted content from the client. For example, use `rm`. For more safety, overwrite the content of the files before deleting them, for example, using `shred -u`.

![Important: shred Does Not Guarantee That Data Is Completely Erased]

Depending on the type of storage media, using `shred` is not a guarantee that all data is completely removed. In particular, SSDs usually employ wear leveling strategies that render `shred` ineffective.
The configuration for the connection from client to server is stored in `/etc/sysconfig/cryptctl-client` and can be edited manually.

The server stores an encryption key for the client partition in `/var/lib/cryptctl/key-db/PARTITION_UUID`.

### 9.3 Checking Partition Unlock Status Using Server-side Commands

When a `cryptctl` client is active, it will send a “heartbeat” to the `cryptctl` server every 10 seconds. If the server does not receive a heartbeat from the client for the length of the timeout configured during the client setup, the server will assume that the client is offline. It will then allow another client to connect (or allow the same client to reconnect after a reboot).

To see the usage status of all keys, use:

```
root # cryptctl list-keys
```

The information under `Num. Users` shows whether the key is currently in use. To see more detail on a single key, use:

```
root # cryptctl show-key UUID
```

This command will show information about mount point, mount options, usage options, the last retrieval of the key and the last three heartbeats from clients.

Additionally, you can use `journalctl` to find logs of when keys were retrieved.

### 9.4 Unlocking Encrypted Partitions Manually

There are two ways of unlocking a partition manually, both of which are run on a client:

- **Online Unlocking.** Online unlocking allows circumventing timeout or user limitations. This method can be used when there is a network connection between client and server but the client could not (yet) unlock the partition automatically. This method will unlock all encrypted partitions on a machine.
To use it, run `cryptctl online-unlock`. Be prepared to enter the password specified when setting up the server.

- **Offline Unlocking.** This method can be used when a client cannot or must not be brought online to communicate with its server. The encryption key from the server must still be available. This method is meant as a last resort only and can only unlock a single partition at a time.
  To use it, run `cryptctl offline-unlock`. The server's key file for the requisite partition (`/var/lib/cryptctl/keydb/PARTITION_UUID`) needs to be available on the client.

## 9.5 Maintenance Downtime Procedure

To ensure that partitions cannot be decrypted during a maintenance downtime, turn off the client and disable the `cryptctl` server. You can do so by either:

- **Stopping the service `cryptctl-server`:**

  ```bash
  root # systemctl stop cryptctl-server
  ```

- **Unplugging the `cryptctl` server from the network.**

## 9.6 For More Information

For more information, also see the project home page [https://github.com/HouzuGuo/cryptctl/](https://github.com/HouzuGuo/cryptctl/).
10 Protecting Against Malware With ClamSAP

ClamSAP integrates the ClamAV anti-malware toolkit into SAP NetWeaver and SAP Mobile Platform applications. ClamSAP is a shared library that links between ClamAV and the SAP NetWeaver Virus Scan Interface (NW-VSI). The version of ClamSAP shipped with SUSE Linux Enterprise Server for SAP Applications 12 SP4 supports NW-VSI version 2.0.

10.1 Installing ClamSAP

1. On the application host, install the packages for ClamAV and ClamSAP. To do so, use the command:

   ```
   tux > sudo zypper install clamav clamsap
   ```

2. Before you can enable the daemon `clamd`, initialize the malware database:

   ```
   tux > sudo freshclam
   ```

3. Start the service `clamd`:

   ```
   tux > sudo systemctl start clamd
   ```

4. Check the status of the service `clamd` with:

   ```
   tux > systemctl status clamd
   ● clamd.service - ClamAV Antivirus Daemon
     Loaded: loaded (/usr/lib/systemd/system/clamd.service; enabled; vendor preset: disabled)
     Active: active (running) since Tue 2017-04-11 10:33:03 UTC; 24h ago
     [...]
   ```

10.2 Creating a Virus Scanner Group in SAP NetWeaver

1. Log in to the SAP NetWeaver installation through the GUI. Do not log in as a DDIC or SAP* user, because the virus scanner needs to be configured cross-client.
2. Create a Virus Scanner Group using the transaction VSCANGROUP.

3. To switch from view mode to change mode, click the button Change View (.Mapper).
   Confirm the message This table is cross-client by clicking the check mark. The table is now editable.

4. Select the first empty row. In the text box Scanner Group, specify CLAMSAPVSI. Under Group Text, specify CLAMSAP.
   Make sure that Business Add-in is not checked.

5. To save the form, click the button Save (Save).

10.3 Setting Up the ClamSAP Library in SAP NetWeaver

1. In the SAP NetWeaver GUI, call the transaction VSCAN.

2. To switch from view mode to change mode, click the button Change View (Mapper).
   Confirm the message This table is cross-client by clicking the check mark. The table is now editable.

3. Click New entries.
4. Fill in the form accordingly:

- **Provider Type**: Adapter (Virus Scan Adapter)

- **Provider Name**: VSA_HOSTNAME (for example: VSA_SAPSERVER)

- **Scanner Group**: The name of the scanner group that you set up in Section 10.2, “Creating a Virus Scanner Group in SAP NetWeaver” (for example: CLAMSAPVSI)

- **Server**: HOSTNAME_SID_INSTANCE_NUMBER (for example: SAPSERVER_P04_00)

- **Adapter Path**: libclamsap.so

5. To save the form, click the button  

10.4 Engaging ClamSAP

To run ClamSAP, go to the transaction VSCAN. Then click Start.
Afterward, a summary will be displayed, including details of the ClamSAP and ClamAV (shown in Figure 10.2, “Summary of ClamSAP Data”).
10.5 For More Information

For more information, also see the project home page https://sourceforge.net/projects/clamsap/.
11 Connecting via RDP

If you installed SLES for SAP with the RDP option activated or if you installed from a KIWI image, RDP is enabled on the machine via the service `xrdp`. Alternatively, you can enable RDP later as described at the end of this section.

You can connect using any software that supports RDP, such as:

- **Linux**: Vinagre (available in SUSE Linux Enterprise Desktop/SLE Workstation Extension and openSUSE) or Remmina (available in openSUSE)
- **Windows**: Remote Desktop Connection

⚠️ Important: Connection Parameters

Make sure to set up the connection with the following parameters:

- **Port**: 3389
- **Color Depth**: 16-bit or 24-bit only

**PROCEDURE 11.1: SETTING UP RDP**

If you have not set up an RDP connection during the installation, you can also do so later using the following instructions.

1. First, create an exception for the firewall. Start by creating a file that sets up the port that needs to be opened for RDP.
   
   As `root`, create a new file under `/etc/sysconfig/SuSEfirewall2.d/services/` with the name `xrdp` and the following content:

   ```
   ## Name: Remote Desktop Protocol
   TCP="3389"
   ```

2. Open the file `/etc/sysconfig/SuSEfirewall2` and change the lines for the settings `FW_CONFIGURATIONS_EXT`, `FW_CONFIGURATIONS_DMZ`, and `FW_CONFIGURATIONS_INT` to include `xrdp`. If there are no other services enabled, the respective lines should read:

   ```
   FW_CONFIGURATIONS_EXT="xrdp"
   FW_CONFIGURATIONS_DMZ="xrdp"
   FW_CONFIGURATIONS_INT="xrdp"
   ```
If there are other services, separate them within the quotes using a space character.

3. Now set up `xrdp` itself.
   If the package `xrdp` is not installed, install it:
   
   ```
   root # zypper install xrdp
   ```

4. Enable and start the service:
   ```
   root # systemctl restart SuSEfirewall2
   ```

5. Enable and start the service:
   ```
   root # systemctl enable xrdp
   root # systemctl start xrdp
   ```

You can now connect to the machine.
12 Creating Operating System Images

There are multiple ways to create custom operating system images from SUSE Linux Enterprise Server for SAP Applications. The preferred way is generally to use KIWI which ingests an XML configuration file and then runs fully automatically.

Alternatively, you can also create an image from an existing installation that is cleaned up before re-use.

12.1 Creating Images with KIWI

KIWI is a tool to create operating system images that can be easily copied to new physical or virtual machines. This section will present information on creating SLES for SAP images with KIWI.

SUSE Linux Enterprise Server for SAP Applications now supports creating images with KIWI using the template from the package `kiwi-template-sap`. However, there are certain restrictions in the current implementation:

- Only building VMX disk images is supported. Building other image types is not supported.
- You must provide an ISO image of SUSE Linux Enterprise Server for SAP Applications at `/tmp/SLES4SAP.iso`, as the Open Build Service does not contain all necessary packages.

To build a basic image, use the following two commands:

1. Build the root file system:

   ```
   root # kiwi -p SLES4SAP --root fsroot
   ```

2. Build the VMX image:

   ```
   root # kiwi --create fsroot --type vmx -d build
   ```

To enable running graphical installations using SAPinst, the default settings of the image enable the following:

- Installation of an IceWM desktop
- The service `xrdp` is started automatically, so you can connect to the machine via RDP.

For more information, see Chapter 11, Connecting via RDP.
For more information about KIWI and SLES for SAP:

- On the KIWI configuration for SLES for SAP, see `/usr/share/kiwi/image/SLES4SAP/README`.
- On KIWI in general, see the openSUSE-KIWI Image System Cookbook (https://doc.opensuse.org/projects/kiwi/doc/).

### 12.2 Cleaning Up an Instance Before Using It as a Master Image

In some cases, it makes sense to use an image of an already-configured master instance on multiple systems instead of generating a KIWI image from scratch. For example, when your image needs to contain additional software or configuration that cannot be installed using KIWI. However, normally such an image would contain certain configuration data that should not be copied along with the rest of the system.

To avoid needing to clean up manually, use the script `clone-master-clean-up` (available from the package of the same name).

It deletes the following data automatically:

- Swap device (zero-wiped, then re-enabled)
- SUSE registration information and repositories from SUSE, and the Zypper ID
- User and host SSH keys and domain and host names
- The generated _HANA-Firewall_ script (but not the configuration itself)
- Shell history, mails, cron jobs, temporary files (`/tmp`, `/var/tmp`), log files (`/var/log`), random seeds, _systemd_ Journal, _collectd_ statistics, _postfix_ configuration, parts of `/root`
- `/var/cache`, `/var/crash`, `/var/lib/systemd/coredump`

Additionally, the following configuration is restored to defaults:

- Network interfaces that do not use DHCP and network configuration (`/etc/hostname`, `/etc/hosts`, and `/etc/resolv.conf`)
- _sudo_ settings
Additionally, you can choose to set up a new root password. UUID-based entries in /etc/fstab are replaced by device strings. This script also ensures that, if the first-boot section of the installation workflow was used for the original installation, it is run again on the next boot.

12.2.1 Configuring clone-master-clean-up

Before running clone-master-clean-up, the script can be configured in the following ways:

- To configure the script to not clean up certain data, use the configuration file /etc/sysconfig/clone-master-clean-up. This file also gives short explanations of the available options.

- To configure the script to clean up additional directories or files, create a list with the absolute paths of such directories and files:

  ```
  /additional/file/to/delete.now
  /additional/directory/to/remove
  ```

  Save this list as /var/adm/clone-master-clean-up/custom_remove.

12.2.2 Using clone-master-clean-up

To use the script, do:

```bash
root # clone-master-clean-up
```

Then follow the instructions.

12.2.3 For More Information

The following sources provide additional information about clone-master-clean-up:

- For general information, see the man page clone-master-clean-up.

- For information on which files and directories might additionally be useful to delete, see /var/adm/clone-master-clean-up/custom_remove.template.
13 Important Log Files

The most important files for this product are:

- The SAP Installation Wizard is a YaST module. You can find its log entries in `/var/log/YaST/y2log`.

- All SAP knowledge is bundled in a library. You can find its log entries in `/var/log/SAPmedia.log`.

- You can find log files related to auto-installation in `/var/adm/autoinstall/logs`.
A Additional Software for SLES for SAP

SUSE Linux Enterprise Server for SAP Applications makes it easy to install software that is not included with your subscription:

- *SUSE Connect Program* allows installing packages created and supported by third parties, specifically for SLES for SAP. It also gives easy access to third-party trainings and support. See Section A.1, “SUSE Connect Program”.

- SUSE Package Hub allows installation of packages created by SUSE Linux Enterprise community without support. See Section A.2, “SUSE Package Hub”.

A.1 SUSE Connect Program

Start SUSE Connect Program from the YaST control center using *SUSE Connect Program*. Choose from the available options. To enable a software repository, click *Add repository*.

All software enabled by SUSE Connect Program originates from third parties. For support, contact the vendor in question. SUSE does not provide support for these offerings.

Note: SUSEConnect command-line tool

The *SUSEConnect* command-line tool is a separate tool with a different purpose: It allows you to register installations of SUSE products.
A.2  SUSE Package Hub

SUSE Package Hub provides many packages for SLE that were previously only available on openSUSE. Packages from SUSE Package Hub are created by the community and come without support. The selection includes, for example:

- The R programming language
- The Haskell programming language
- The KDE 5 desktop

To enable SUSE Package Hub, add the repository as described at https://package-hub.suse.com/how-to-use/.

For more information, see the SUSE Package Hub Web site at https://packagehub.suse.com.
Partitioning for the SAP System Using AutoYaST

Partitioning for the SAP system is controlled by the files from the directory `/usr/share/YaST2/include/sap-installation-wizard/`. The following files can be used:

- **SAP NetWeaver or SAP S/4HANA Application Server Installation.** `base_partitioning.xml`
- **SAP HANA or SAP S/4HANA Database Server Installation.** `hana_partitioning.xml`
- **SAP HANA or SAP S/4HANA Database Server Installation on SAP BusinessOne-Certified Hardware.** hardware-specific partitioning file

The files will be chosen as defined in `/etc/sap-installation-wizard.xml`. Here, the content of the element `partitioning` is decisive.

If the installation is, for example, based on HA or a distributed database, no partitioning is needed. In this case, `partitioning` is set to `NO` and the file `base_partitioning.xml` is used.

**Note: `autoinst.xml` Cannot Be Used Here**

`autoinst.xml` is only used for the installation of the operating system. It cannot control the partitioning for the SAP system.

The files that control partitioning are AutoYaST control files that contain a `partitioning` section only. However, these files allow using several extensions to the AutoYaST format:

- **If the `partitioning_defined` tag is set to `true`, the partitioning will be performed without any user interaction.**
  
  By default, this is only used when creating SAP HANA file systems on systems certified for SAP HANA (such as from Dell, Fujitsu, HP, IBM, or Lenovo).

- **For every partition, you can specify the `size_min` tag. The size value can be given as a string in the format of `RAM*N`. This way you can specify how large the partition should minimally be (`N` times the size of the available memory (`RAM`)).**

**PROCEDURE B.1: CREATING A CUSTOM SAP PARTITIONING SETUP**

The steps below illustrates how to create a partitioning setup for TREX. However, creating a partitioning setup for other applications works analogously.
1. In `/usr/share/YaST2/include/sap-installation-wizard/`, create a new XML file. Name it `TREX_partitioning.xml`, for example.

2. Copy the content of `base_partitioning.xml` to your new file and adapt the new file to your needs.

3. Finally, adapt `/etc/sap-installation-wizard.xml` to include your custom file. In the `listitem` for `TREX`, insert the following line:

   ```xml
   <partitioning>TREX_partitioning</partitioning>
   ```

**Important: Do Not Edit `base_partitioning.xml`**

Do not edit `base_partitioning.xml` directly. With the next update, this file will be overwritten.

For more information about partitioning with AutoYaST, see *AutoYaST Guide, Chapter “Partitioning”* ([https://www.suse.com/documentation/sles-12/](https://www.suse.com/documentation/sles-12/)).
C Supplementary Media

Supplementary Media allow partners or customers to add their own tasks or workflows to the Installation Wizard.

This is done by adding an XML file which will be part of an AutoYaST XML file. To be included in the workflow, this file must be called `product.xml`.

This can be used for various types of additions, such as adding your own RPMs, running your own scripts, setting up a cluster file system or creating your own dialogs and scripts.

C.1 `product.xml`

The `product.xml` file looks like a normal AutoYaST XML file, but with some restrictions.

The restrictions exist because only the parts of the XML that are related to the second stage of the installation are run, as the first stage was executed before.

Both XML files (`autoyast.xml` and `product.xml`) will be merged after the media is read and a “new” AutoYaST XML file is generated on the fly for the additional workflow.

The following areas or sections will be merged:

```
<general>
  <ask-list> 1
  ...
<software> 2
  <post-packages>
    ...
<scripts>
  <chroot-scripts> 3
  <post-scripts> 4
  <init-scripts> 5
  ...
```

1 see Section C.2, “Own AutoYaST Ask Dialogs”
2 see Section C.3, “Installing Additional Packages”
3 after the package installation, before the first boot
4 during the first boot of the installed system, no services running
5 during the first boot of the installed system, all services up and running

All other sections will be replaced.
For more information about customization options, see *AutoYaST Guide, Chapter “Configuration and Installation Options”, Section “Custom User Scripts”* (https://www.suse.com/documentation/sles-12/).

### C.2 Own AutoYaST Ask Dialogs

For more information about the “Ask” feature of AutoYaST, see *AutoYaST Guide, Chapter “Configuration and Installation Options”, Section “Ask the User for Values During Installation”* (https://www.suse.com/documentation/sles-12/).

For the Supplementary Media, you can only use dialogs within the `cont` stage (`<stage>cont</stage>`), which means they are executed after the first reboot.

Your file with the dialogs will be merged with the base AutoYaST XML file.

As a best practice, your dialog should have a dialog number and an element number, best with steps of 10. This helps to include later additions and could be used as targets for jumping over a dialog or element dependent on decisions. We also use this in our base dialogs and if you provide the right dialog number and element number, you can place your dialog between our base dialogs.

You can store the answer to a question in a file, to use it in one of your scripts later. Be aware that you must use the prefix `/tmp/ay` for this, because the Installation Wizard will copy such files from the `/tmp` directory to the directory where your media data also will be copied. This is done because the next Supplementary Media could have the same dialogs or same answer file names and would overwrite the values saved here.

Here is an example with several options:

```xml
<?xml version="1.0"?>
<!DOCTYPE profile>
<profile xmlns="http://www.suse.com/1.0/yast2ns"
         xmlns:config="http://www.suse.com/1.0/configns">
  <general>
    <ask-list config:type="list">
      <ask>
        <stage>cont</stage>
        <dialog config:type="integer">20</dialog>
        <element config:type="integer">10</element>
        <question>What is your name?</question>
        <default>Enter your name here</default>
        <help>Please enter your full name within the field</help>
        <file>/tmp/ay_q_my_name</file>
      </ask>
    </ask-list>
  </general>
</profile>
```
C.3 Installing Additional Packages

You can also install RPM packages within the `product.xml` file. To do this, you can use the `<post-packages>` element for installation in stage 2.

For more information, see AutoYaST Guide, Chapter “Configuration and Installation Options”, Section “Installing Packages in Stage 2” (https://www.suse.com/documentation/sles-12/). An example looks as follows:

```xml
...<software>
  <post-packages config:type="list">
    <package>yast2-cim</package>
  </post-packages>
</software>
...```

C.4 Example Directory for Supplementary Media

A minimal example for Supplementary Media directory contains only a file called `product.xml`. 
D Documentation Updates

This section contains information about documentation content changes made to the SUSE Linux Enterprise Server for SAP Applications Guide.

This document was updated on the following dates:

- Section D.1, “May 06, 2019—SLES for SAP 12 SP4 FCS Documentation Release”
- Section D.2, “October 25, 2018—SLES for SAP 12 SP4 FCS Documentation Release”
- Section D.3, “October 25, 2018—SLES for SAP 12 SP4 Initial Documentation Release”
- Section D.4, “April 25, 2018—SLES for SAP 12 SP3 Documentation Update”
- Section D.5, “November 1, 2017—SLES for SAP 12 SP3 Documentation Update”
- Section D.6, “September 7, 2017—SLES for SAP 12 SP3 FCS”
- Section D.7, “May 10, 2017—SLES for SAP 12 SP2 Documentation Update”
- Section D.8, “December 07, 2016—SLES for SAP 12 SP2 Documentation Update”
- Section D.9, “November 07, 2016—SLES for SAP 12 SP2 FCS”
- Section D.10, “March 23, 2016”
- Section D.11, “February 29, 2016”
- Section D.12, “February 15, 2016”
- Section D.13, “May 29, 2015”
- Section D.14, “April 29, 2015”
- Section D.15, “October 28, 2013”

D.1 May 06, 2019—SLES for SAP 12 SP4 FCS Documentation Release

Updates were made to the following sections. The changes are explained below.

Section 1.3, “Included Services”

Updated information about ESPOS.
Section 7.3, “Tuning Systems with saptune”

Removed sentence discouraging use of saptune.

Section 7.2, “Tuning Systems with sapconf”

Fixed erroneous uses of the profile name sapconf that should have read sap-netweaver.

D.2 October 25, 2018—SLES for SAP 12 SP4 FCS Documentation Release

Updates were made to the following sections. The changes are explained below.

Section 2.1, “Hardware Requirements”
Corrected hard disk and RAM requirements (bsc#1116907).

Section 6.3, “Unattended Installation of Cluster Servers”
Added section about unattended installation of HANA-SR cluster (FATE#325957).

Section 7.2, “Tuning Systems with sapconf”
Further added to sapconf section (FATE#325785).

D.3 October 25, 2018—SLES for SAP 12 SP4 Initial Documentation Release

Updates were made to the following sections. The changes are explained below.

Section 1.3, “Included Services”
Fixed typo (bsc#1088879).

Section 7.2, “Tuning Systems with sapconf”
Amended for sapconf 4.1.11 and up (FATE#325785).

D.4 April 25, 2018—SLES for SAP 12 SP3 Documentation Update

Updates were made to the following sections. The changes are explained below.
Section 1.3, “Included Services”
Fixed typo (bsc#1088879).

Section 6.2, “Setup”
Fixed misleading content: Other fencing types supported but not in YaST (bsc#1086628).

D.5 November 1, 2017—SLES for SAP 12 SP3 Documentation Update

Updates were made to the following sections. The changes are explained below.

Section 1.2, “Software Repository Setup”
Added note about ESPOS updates via regular update repositories (bsc#1062335).

D.6 September 7, 2017—SLES for SAP 12 SP3 FCS

Updates were made to the following sections. The changes are explained below.

Chapter 2, Planning the Installation
Added link to SAP help and support portals (documentation comment #33499).

Chapter 2, Planning the Installation, Chapter 4, Installing SAP Applications
Updated chapters with information about support for SAP HANA MDC and SAP HANA TDI (FATE#322281, FATE#320408).

Section 3.1, “Using the Installation Workflow”
Updated section with reference to description of installation on POWER in SLES documentation (FATE#320639).

Chapter 9, Encrypting Directories Using cryptctl
Updated chapter with information about support client certificates and KMIP (FATE#322293, FATE#322979).

Section 3.4, “Converting a SLES Installation to a SLES for SAP Installation”
Added section about converting from SLES to SLES for SAP (FATE#320636, FATE#320568).

Chapter 7, Tuning
Updated list of profiles integrated into `saptune` and `sapconf` (FATE#320359). Created own section for `sapconf`.

Section 12.2, “Cleaning Up an Instance Before Using It as a Master Image”
Clarified usage of `clone-master-clean-up` (DocComment#32698). Added information about new configuration options (FATE#322066).

D.7 May 10, 2017—SLES for SAP 12 SP2 Documentation Update

Updates were made to the following sections. The changes are explained below.

Section 1.1, “Software Components”
Added links to project Web sites (FATE#323178).

Section 1.2, “Software Repository Setup”, 
Section 1.3, “Included Services”
Added information about repositories and support for extensions and modules (bsc#1022275).

Section 6.2, “Setup”
`softdog` is supported but not recommended (bsc#1022511).

Section 7.3, “Tuning Systems with saptune”
Documented disabling `saptune/sapconf` (FATE#322069).

Chapter 10, Protecting Against Malware With ClamSAP
Added new chapter (FATE#322612).

Section A.2, “SUSE Package Hub”
Added link to official usage instructions on the Web.

D.8 December 07, 2016—SLES for SAP 12 SP2 Documentation Update

Updates were made to the following sections. The changes are explained below.

Section 2.1, “Hardware Requirements”
Clarified RAM requirements.

**Chapter 6, Setting Up an SAP HANA Cluster**
Added new chapter (FATE#319068).

**Section 8.2, “Configuring HANA-Firewall”**
Updated UI description (FATE#320376, FATE#320564).

**Section 8.3, “SAProuter Integration”**
Added new section (FATE#320566).

**Appendix A, Additional Software for SLES for SAP**
Added new appendix (FATE#320373).

**Chapter 7, Tuning, Chapter 9, Encrypting Directories Using cryptctl**
Clarifications.

---

**D.9  November 07, 2016—SLES for SAP 12 SP2 FCS**

Updates were made to the following sections. The changes are explained below.

**Section 1.1, “Software Components”**
Updated list of components.

**Section 1.2, “Software Repository Setup”**
Added section (bsc#320632).

**Chapter 3, Installing the Operating System, Chapter 4, Installing SAP Applications**
Updated chapters to match new installation wizards. Added list of supported SAP products (FATE#320454).

**Section 4.5, “Partitioning for an SAP Application Without the SAP Installation Wizard”**
Added section (bsc#929623).

**Chapter 7, Tuning, Chapter 8, Firewalling, Chapter 12, Creating Operating System Images, Chapter 13, Important Log Files**
Separated former chapter *Configuration* into smaller chapters.

**Section 7.3, “Tuning Systems with saptune”**
Updated section to refer to saptune (FATE#320361, FATE#320362, FATE#320633).
Chapter 9, Encrypting Directories Using `cryptctl`
Added section (FATE#320367).

Chapter 11, Connecting via RDP
Added section (FATE#320363).

Appendix B, Partitioning for the SAP System Using AutoYaST
Moved parts of Section 2.6.2, “Partitioning for the SAP System (stage 2)” that related to AutoYaST only to a new section.

D.10 March 23, 2016
Updates were made to the following sections. The changes are explained below.

Section 1.1.3.1, “SAPHana Resource Agent”
Clarify wording.

Section 3.3, “Using an External AutoYaST Profile”

D.11 February 29, 2016
Updates were made to the following sections. The changes are explained below.

Section 12.2, “Cleaning Up an Instance Before Using It as a Master Image”
Add new section.

Section 12.1, “Creating Images with KIWI”
Add new section.

Section 2.2, “Downloading the Installation Image”
Clarify that only DVD 1 is necessary for installation (doccomment#30069).

Other updates
Other corrections and small language updates.

D.12 February 15, 2016
Updates were made to the following sections. The changes are explained below.
Updates to the Structure of the Guide

Improve organization of the guide by updating its structure. Chapter 2, Planning the Installation, Chapter 4, Installing SAP Applications, Configuring SUSE Linux Enterprise Server for SAP Applications, and Chapter 5, Setting Up an Installation Server for SAP Media Sets are now chapters instead of sections.

Appendix C, Supplementary Media is now an appendix instead of section.

Section 2.6, “Partitioning” is now a section within Chapter 2, Planning the Installation instead of a chapter.

Merge Section 1.1, “Software Components” and Chapter 5, “SUSE Linux Enterprise Server for SAP Applications Components”.

Move Section 3.2, “Using SLES for SAP Media from the Network” from Chapter 3, “Remote Installation from a Network Server” to Chapter 3, Installing the Operating System.

Move Section 2.5, “Required Data for Installing” from Chapter 3, Installing the Operating System to Chapter 2, Planning the Installation.

Move certain information from Section 1.1.4, “Installation Workflow” to Section 2.4, “Overview of the Installation Workflow”.

Chapter 1, What Is SUSE Linux Enterprise Server for SAP Applications?

Add figure.

Section 1.1.3, “Simplified SAP HANA System Replication Setup”

Add information on supported scenarios.

Section 1.1.6, “Malware Protection with ClamSAP”

Mention added support for NW-VSI 2.0.

Section 1.1.7, “SAP HANA Security”

Add new section.

Section 1.1.8, “Simplified Operations Management”

Add new section.

Section 3.1, “Using the Installation Workflow”

Remove outdated installation options. Update Installation Workflow.

Section 3.3, “Using an External AutoYaST Profile”

Remove information that duplicated.

Chapter 4, Installing SAP Applications

Update Installation Workflow.
Section 8.2, “Configuring HANA-Firewall”
Add new section.

Section 7.3, “Tuning Systems with saptune”
Add new section.

D.13 May 29, 2015

Updates were made to the following sections. The changes are explained below.

Section 1.1, “Software Components”
Add more information on SUSE Linux Enterprise High Availability Extension.
There are also White Papers about SUSE Linux Enterprise High Availability Extension and
SUSE Linux Enterprise Server for SAP Applications.

Chapter 2, Planning the Installation
Provide ISO image download URL.

Section 2.2, “Booting the Installation Medium”
The package scope of the SLES for SAP Applications — Installation is identical to a default
SUSE Linux Enterprise Server installation.

Section 2.3, “SLES for SAP — Installation”
Add note about pre-selected packages in case of registration at this stage of the installation.

Section 2.4.3.5, “Registration”
Add note about pre-selected packages in case of registration at this stage of the installation.

Chapter 4, Installing SAP Applications
Rewrite remote location specification.

Section 2.6, “Partitioning”
SAP HANA requires 2 GB of swap.

Section 1.1.3, “Simplified SAP HANA System Replication Setup”

Section 1.1.7.2, “Hardening Guide for SAP HANA”
D.14  April 29, 2015

Updates were made to the following sections. The changes are explained below.

General
Replace SUSE Linux Enterprise Server 11 references with SUSE Linux Enterprise Server 12 everywhere, and adjust the text according to the new installation flow.

About This Guide
Update feedback information.

Section 3.3, “Using an External AutoYaST Profile”
Add note about loading an external profile via HTTP (https://bugzilla.suse.com/show_bug.cgi?id=925747 #).

D.15  October 28, 2013

Updates were made to the following sections. The changes are explained below.

Chapter 3, Installing the Operating System
Update “Hardware Requirements”, “Hard Disk” space, and adjust the following text accordingly.

Section 2.6, “Partitioning”
New chapter.

Appendix D, Documentation Updates
New appendix.
